1. Introduction

1.1. ReportLab PLUS

ReportLab's solution solves several central problems that ebusinesses face in creating publishing caliber reports that are customized, produced in real time, in volume, and platform independent. Existing reporting tools are limited to database reports, are typically Windows-based, have problematic restrictions on layout and graphic design, and go straight to a printer. More complex publishing systems involve pipelines of applications which are simply too unwieldy for real-time use in large scale environments.

ReportLab's product suite allows direct creation of rich PDF reports on web or application servers in real time. The tools run on any platform, can actively acquire data from any source (XML, flat files, databases, COM/Corba/Java), place no limits on the output, and facilitate electronic delivery and archival. The ReportLab suite lets you define your own business rules to automatically create custom online reports, catalogs, business forms, and other documents.

RML2PDF is a central component of the toolkit: a translator which converts high level XML markup into PDF documents. Report Markup Language describes the precise layout of a printed document, and RML2PDF converts this to a finished document in one step. In a dedicated reporting application, other components of our toolkit handle data acquisition and preparation of the RML document.

RML2PDF on its own also fills a key technology gap. Our full toolkit relies heavily on the Python scripting language. Nevertheless we recognize that IT departments and software houses have their own distinct skill sets and development tools. A company may already have developed a rich 3-tier architecture with the key business data in Java or COM objects on an application server. All they need is the formatting component. They can use exactly the same techniques they use to generate HTML (XSLT, JSP, ASP or anything else) to generate an RML file, and the program turns this into a finished document. Fast.

Unlike a number of other formatting languages, RML aims squarely at corporate needs. Paragraph, table and page styles are kept in independent ‘stylesheets’, allowing reuse and global changes across a family of documents. The table model has been designed for efficient rendering of business data. And a plug-in architecture lets you easily develop and add in custom vector graphics or page templates within the same tool set.

RML2PDF can also work in tandem with our PageCatcher product. PageCatcher is a support tool which extracts graphical elements from PDF files for inclusion in documents generated by RML2PDF or the ReportLab core API. Since any external program with the ability to print can produce PDF files, this means that a ReportLab document can include graphical elements created by virtually any program. These imported elements can be combined freely with text or graphics drawn directly into the document. For example an application can import pages from a government tax form and draw text in the spaces provided to fill in the form. The resulting document can then be combined with a cover letter at the beginning and supporting tabular data at the end -- all in a single PDF document.

1.2. Installation and Use

To avoid duplication, the full installation instructions are always on ReportLab's web site at this address:

http://www.reportlab.com/software/installation/

RML2PDF is a compiled Python programming language module. It can be used with options from a command line, and also has a programmable API interface and may be used as a component of a larger Python language installation. Since Python integrates with a wide variety of other languages, it is also possible to access RML2PDF from C and C++ programs, COM and many other environments.

RML2PDF is delivered as part of ReportLab's 'rlextra' package and licensed under the name ReportLab PLUS. This package depends on our 'reportlab' package and some other open source libraries, all detailed on the above installation page.
RML2PDF requires a license key file to work in production mode. Without the license key each page produced by RML2PDF will be visibly marked as an "evaluation" copy, and the file will be annotated invisibly as produced for evaluation purposes as well. With a valid license key file present, RML2PDF will run in production mode and the PDF file generated will contain the licensing information. You can purchase a ReportLab PLUS license using your user account on our website http://www.reportlab.com. Once we issue you a '.pyc' license file you will need to install it somewhere on your PYTHONPATH so that rml2pdf can find it.

**Running RML2PDF from the command line**

RML2PDF can be run from the command line, provided that you place it on your path. We normally ship this module in compiled (.pyc) format, so you need a Python interpreter of the correct version to run it, and need to know where it was installed. The installation process does not currently register a script for you. On Unix, you may wish to add the directory to your path, or create a wrapper script in your bin directory.

```
python /path/to/rlextra/rml2pdf/rml2pdf.pyc filename.rml
```

On Windows, .pyc files are normally associated with the most-recently-installed Python interpreter, so you could execute this...

```
c:\temp> c:\python26\lib\site-packages\rlextra\rml2pdf\rml2pdf.pyc filename.rml
```

After completing successfully the rml2pdf program will return to a command prompt. The output PDF file should be created in the current working directory.

**Calling RML2PDF from Python**

RML2PDF can also be called directly from your own Python program using the rml2pdf.go(...) entry point.

There are two main ways the 'go' function can be used - either to generate the resulting PDF file on disk in the file system, or to generate it in memory (useful for web applications returning the PDF directly to the user).

This example uses the 'go' function to create the output PDF file on disk:

```python
from rlextra.rml2pdf import rml2pdf
rml = getRML()  # Use your favorite templating laguage here to create the RML string
output = '/tmp/output.pdf'

rml2pdf.go(rml, outputFileName=output)
```

This is an example Django web application view generating a PDF in memory and returning it as the result of an HTTP request:

```python
from django.http import HttpResponse
from rlextra.rml2pdf import rml2pdf
import cStringIO

def getPDF(request):
    """Returns PDF as a binary stream."""

    # Use your favourite templating language here to create the RML string.
    # The generated document might depend on the web request parameters,
    # database lookups and so on - we'll leave that up to you.
    rml = getRML(request)

    buf = cStringIO.StringIO()
rml2pdf.go(rml, outputFileName=buf)
buf.reset()
pdfData = buf.read()

response = HttpResponse(mimetype='application/pdf')
response.write(pdfData)
response['Content-Disposition'] = 'attachment; filename=output.pdf'
return response

The 'go' function has the following interface:

def go(xmlInputText, outputFileName=None, outDir=None, dtdDir=None,
       passLimit=2, permitEvaluations=1, ignoreDefaults=0,
       pageCallBack=None,
       progressCallBack=None,
       preppyDictionary=None, preppyIterations=1,
       dynamicRml=0, dynamicRmlNameSpace={},
       encryption=None,
       saveRml=None,
       parseOnly=False,
):  

- xmlInputText must be a string which contains the RML specification for the PDF document to be generated.
- outputFileName when specified overrides any output file name specified in the xml input text. You may also pass in a file-like object (e.g. a StringIO, file object or web request buffer), in which case nothing is written to disk.
- outDir (output directory) parameter when present specifies the directory in which to place the output file.
- dtdDir is an optional DTD directory parameter which specifies the directory containing the DTD for the current version of RML.
- passLimit of None means "keep trying until done", of 3 means, "try 3 times then quit".
- permitEvaluations when false disallows the evalString tag for security (e.g. web apps).
- ignoreDefaults 1 means "do one pass and use the default values where values are not found".
- pageCallBack is a callback to execute on final formatting of each page - used for counting number of pages.
- progressCallBack is a cleverer callback; see the progressCB function in reportlab/platypus/doctemplate.
- preppyDictionary if set to a dictionary indicates that the xmlInputText should be preprocessed using preppy with the preppyDictionary as argument. If preppyDictionary is not None and preppyIterations is >1 then the preppy preprocessing will be repeated preppyIterations times (max of 3) with the same dict, to generate, e.g., table of contents.
- preppyIterations - see preppyDictionary.
- dynamicRml is an optional boolean field for whether the RML can be dynamically altered.
- dynamicRmlNameSpace is for use with dynamicRml. It's a dictionary which you can add variables to for processing.
- encryption if set it must be an encryption object, for example:
rlextra.utils.pdfencrypt.StandardEncryption("User", "Owner",
canPrint=0, canModify=0, canCopy=0, canAnnotate=0).
- saveRml is useful for debugging dynamically generated RML. Specify a filename where the RML should be saved.
• parseOnly if set to True, will only parse the RML and not generate a PDF.

It is also possible to call rml2pdf from other programming languages (such as C++) by using standard methods for calling a python callable. See the Python Language Embedding and Extension manuals.

NB it is also possible to use the userPass, ownerPass, permissions & encryptionStrength attributes of the document tag to make rml2pdf create an encrypted PDF.

For further information regarding the installation of your version of RML2PDF please see the release notes and READMEs that come with the package.

1.3. What is RML?
RML is the Report Markup Language - a member of the XML family of languages, and the XML dialect used by rml2pdf to produce documents in Adobe's Portable Document Format (PDF).

RML documents can be written automatically by a program or manually using any word processor that can output text files (e.g. using a "Save as Text" option from the save menu). Since RML documents are basic text files, they can be created on the fly by scripts in Python, Perl, or almost any other language.

RML makes creating documents in PDF as simple as creating a basic web page - RML is as easy to write as HTML, and uses "tags" just like HTML. It is much easier than trying to write PDF programmatically.

1.4. What is this document?
This document is a user guide and tutorial for RML. It deals with RML as specified in the RML DTD - rml.dtd. If your installation of RML uses a later version, you will need a later version of the DTD and of this tutorial. Look on the ReportLab website (http://www.reportlab.com) for more details.

This document has been generated from RML. If you need another example of RML in action, look at the file "rml_user_guide.rml" to see how this file was produced.

1.5. Who is this document aimed at?
This document is aimed at anyone who needs to write RML. It assumes that you have some experience with some form of programming or scripting. Basic HTML is fine.

You do not have to be employed as a programmer or have extensive programming skills for this guide to make sense. We have tried to keep it as simple as possible and to minimise confusion.

1.6. Conventions used in this document

It is more technically correct to call the various items in RML "elements", as you do in XML. However, since we're assuming that more people know basic HTML than XML, we'll call them "tags" rather than elements in this guide.

There are also a couple of typographical conventions we'll be using:

**constant width**

Throughout this User Guide, we'll be using a constant width typeface to highlight any literal element of RML (such as tag names or attributes for tags) when they appear in the text.

**8 point Courier**

A smaller constant width font is used for code snippets (short one or two line examples of what RML commands look like) and code examples (longer examples of RML which usually have an illustration
of the output they produce).
Part I - The Basics

2. Pages and page structures

2.1. XML syntax and RML

As with every XML dialect, RML requires correct XML syntax. If you are familiar with HTML, you should pay special attention to the differences between XML syntax and some of the more forgiving constructs allowed in HTML.

- Attribute values must be enclosed in quotation marks. (e.g. you would have to use `<document filename="outfile.pdf">`, since you couldn't get away with `<document filename=outfile.pdf>`)
- A non-empty element must have both an opening and a closing tag. (e.g. a `<document>` tag must be matched by a matching `</document>` tag). "Empty" elements are those that don't have any content, and are closed with a "" at the end of the same tag rather than having a separate closing tag. (e.g. `<getName id="Header.Title"/>`)
- Tags must be nested correctly. (i.e. "<b><i>text</b></i>" isn't valid, but "<b><i>text</i></b>" is.)
- On the whole, whitespace is ignored in RML. Except inside strings, you can format and indent your RML documents in whatever way you consider most readable. (Inside text strings, whitespace is seen as equivalent to a single space and line breaks are added automatically as needed during formatting. Other than that, what you type is what is displayed on the page).
- RML is case-sensitive. "Upper Case" is different from "upper case", "UPPER CASE" and "UpPeR CaSe". The capitalization in the tag names is important.

2.2. The prolog

Every RML document must start with a number of lines:

```xml
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM "rml.dtd">
```

This is called the prolog - you can think of it as the document 'header'.

```xml
<?xml ... standalone="no" ?>

This line is the XML declaration. This is optional, but recommended.

version="1.0"

This attribute tells the parser which version of XML it should use - in this case 1.0.

standalone="no"

This tells the parser that it needs an external Document Type Definition (more on DTDs below).

encoding="iso-8859-1"

The "encoding" attribute sets the encoding you want the PDF file to use. The ISO-8859-1 encoding covers the character set known as "US-ASCII", plus things like the accented characters used in most Western European Languages and some control characters and graphical characters. ISO-8859-1 is also known as "Latin-1" (or "Latin Alphabet No 1"). Other common encodings are utf-8 (same as US-ASCII for "normal" characters like A-Z and 0-9, but also covers the whole Unicode character set) and cp1252 (a Microsoft Windows variant of ISO-8859-1). You may use any encoding you wish with RML, as long as the encoding attribute here matches the encoding you actually used to write the RML file!
This line tells the parser where the Document Type Definition is located. The DTD formally specifies the syntax of RML.

For documents written in RML, the DTD should always be the current version of rml.dtd. (The rml DTD should always be called rml.dtd.)

Unlike other dialects of XML, RML does not allow you to provide relative paths to the DTD, nor a full URL. It must always be the name of the DTD, which must live in the same directory as the exe or python program rml2pdf.

This makes it easy to predict where the RML DTD will be and prevents you using an old DTD that happens to be sitting around your disk somewhere. It also allows us to make sure that when you create a file with RML, the PDF document will be created in the same directory as the RML file, and to allow relative pathnames in the document tag.

The prolog section is common to all XML documents. In addition to this, RML requires another line following the prolog:

"<document filename="outfile.pdf">

This line gives the name that you want the output PDF file created with. This line also starts the document proper - and must be matched by a </document> tag as the last line in the document, in the same way that an HTML file is bracketed by <HTML> and </HTML>.

The filename you give can just be a simple filename, a relative path (eg ..\..\myDoc.pdf will create it in the directory two levels up from the one your RML document is in), or a full pathname (eg C:\output_files\pdf\myProject\myDocument.pdf or /tmp/user1/myScratchFile.pdf). If you just supply a filename, the output file will be created in the same directory as your RML file. (The same principle works with anywhere else you may need to give a filename - they are relative to where the document lives on your disk, not to where rml2pdf is).

The <document> tag has three other attributes. compression specifies whether the produced PDF should be compressed if at all possible. It can take the values 0 | 1 | default for off, on or use the site-wide default (as specified in reportlab_rl_config). invariant determines whether the produced PDF should be invariant with respect to the date and the exact contents. It can take the values 0 | 1 | default for off, on or use the site-wide default (as specified in reportlab_rl_config). debug determines whether debugging/logging mode should be used during document production. It can take the values 0 | 1 for off or on.
2.3. Document forms: stylesheet/pageDrawing vs template/stylesheet/story

There are two possible valid structures for your document to have, depending on how simple you want it to be.

For very simple documents, you need the prolog, followed by a stylesheet and any number of pageDrawings. A pageDrawing is a graphical element on the page, or simple text string (i.e. it is just placed onto the page in the location you specify, and no attempt is made to check if it flows off the page).

EXAMPLE 1

```xml
<!DOCTYPE document SYSTEM "rml.dtd">
<document filename="example_1.pdf">
  <stylesheet>
  </stylesheet>
  <pageDrawing>
    <drawCentredString x="4.1in" y="5.8in">
      Hello World.
    </drawCentredString>
  </pageDrawing>
</document>
```

(All the examples given in this document can be found online at http://www.reportlab.com/documentation/rml-samples/ or in the mercurial repository at https://bitbucket.org/rptlab/rlextra-examples which is a copy of the tests in our main repository.)

Figure 1: Output from EXAMPLE 1
This is the most basic RML document you can get. It is the traditional "Hello World". All it does is place the string of text "Hello World" into the middle of your A4 page. Not very useful in the real world, but enough to show you how simple RML can be.

Notice how it does have a stylesheet, but it is empty. Stylesheets are mandatory, but they don't need to actually contain anything. Also notice how in the drawCenteredString tag, the co-ordinates are enclosed in quotation marks - they are attributes, and so need to live inside quotes. And if you look at the drawCenteredString tag, these attributes are inside the tag (actually inside the angle brackets), then the content of the string comes after it, then the tag is closed by its matching </drawCenteredString> tag. All tags with content need their matching closing tag - the <document> and <stylesheet> tags are also parts of matching pairs.

One last thing to notice is the DOCTYPE line - for all these examples, we are assuming that the DTD is in the same directory as the example file itself. This may not always be the case.

For a more complex RML document, you can use the more powerful template/stylesheet/story form of document. In this, a file contains the following three sections:

- a template
- a stylesheet
- a story

The template tells rml2pdf what should be on the page: headers, footers, any graphic elements you use as a background.

The stylesheet is where the styles for a document are set. This tells the parser what fonts to use for paragraphs and paragraph headers, how to format tables and other things of that nature.

The story is where the "meat" of the document is. Just like in a newspaper, the story is the bit you want people to read, as opposed to design elements or page markup. As such, this is where headers, paragraphs and the actual text is contained.

```
<!DOCTYPE document SYSTEM "rml.dtd">
<document filename="example_2.pdf">
  <template>
    <pageTemplate id="main">
      <frame id="first" x1="72" y1="72" width="451" height="698"/>
    </pageTemplate>
  </template>
  <stylesheet>
  </stylesheet>
  <!-- The story starts below this comment -->
  <para>This is the "story". This is the part of the RML document where your text is placed. It should be enclosed in "para" and "/para" tags to turn it into paragraphs.</para>
</document>
```

Figure 2: Output from EXAMPLE 2

EXAMPLE 2
The `<pageTemplate>`, `<pageGraphics>`, `<frame>` and `<paraStyle>` tags will all be covered in more detail later on in this guide.

Paragraphs start with a `<para>` tag and are closed with a `</para>` tag. Their appearance can be controlled with the `<paraStyle>` tag.

RML allows you to use comments in the RML code. These are not displayed in the output PDF file. Just like in HTML, they start with a `<!--` and are terminated with a `-->`. Unlike other tags, comments cannot be nested. In fact, you can't even have the characters `-->` inside the `<!--` section.
3. Basic Text Operations

3.1. Coordinates and Measurements

In RML, the page origin is in the bottom left hand corner (0,0). Any point on the page can be specified by a pair of numbers - a pair of X,Y co-ordinates. The X co-ordinate states how far to the right the point is and the Y co-ordinate states how far up it is.

When an RML element has co-ordinates, the co-ordinate origin is the lower left corner. In the case of elements in a pageGraphic, the origin of the lower left corner of the page. For elements within an <illustration>, the origin is the lower left corner of the bounding box declared by the <illustration>.

These co-ordinates (and any other measurements in an RML document) can be given in one of four units. Inches use the term 'in', centimetres use the term 'cm', and millimetres use the term 'mm'. If no unit is specified, RML will assume that you are giving a measurement in points - one point is 1/72 of an inch. You can also explicitly use points with the term 'pt'.

As an example, the following pairs of co-ordinates all refer to the same point. Notice that there is no space between the number and any unit that follows it.

(4.5in, 1in)
(11.43cm, 2.54cm)
(324, 72)

You can mix and match these units within RML, though it generally isn't a good idea to do so. The co-ordinate pair (3.5in, 3.5cm) is valid, and won't confuse the RML parser - but it may well confuse you.

3.2. Using Colors

There are three ways to specify colors in RML:

- by red/green/blue value (e.g. "#ff0000" or ";(0.0,0.0,1.0)"
- by cyan/magenta/yellow/black value (e.g. "#ff99001f" or ";(1.0,0.6,0.0,0.1)"
- by color name using standard HTML names

The RGB or additive color specification follows the way a computer screen adds different levels of the red, green, or blue light to make any color. White is formed by turning all three lights on full (1,1,1).

The CMYK or subtractive method follows the way a printer mixes three pigments (cyan, magenta, and yellow) to form colors. Because mixing chemicals is more difficult than combining light there is a fourth parameter for darkness. A chemical combination of the CMY pigments almost never makes a perfect black - instead producing a muddy brown - so, to get black printers use a direct black ink rather than use the CMY pigments.

The name CMYK comes from the name of the four colors used: Cyan, Magenta, Yellow and "Key" - a term sometimes used by printers to refer to black.

Because CMYK maps more directly to the way printer hardware works it may be the case that colors specified in CMYK will provide better fidelity and better control when printed.

The color names which RML recognizes are mostly drawn from the HTML specification. (For a list of these color names recognized by RML, see Appendix A).

[NOTE: Currently, while RML supports specifying colors by CMYK value, rml2pdf hasn't yet implemented it. If you try, you well get a ValueError and the error message "cmyk not implemented yet"].
### 3.3. Using fonts

Font names are given in the following format:

```
Fontname-style
```

where fontname is the name of the font (e.g. Courier), and the style is its appearance (eg, Oblique, BoldOblique). The only fonts supplied with Adobe’s Acrobat Reader are the “14 standard fonts”. These 14 standard fonts are:

- Courier
- Courier-Bold
- Courier-BoldOblique
- Courier-Oblique
- Helvetica
- Helvetica-Bold
- Helvetica-BoldOblique
- Helvetica-Oblique
- Symbol
- Times-Bold
- Times-BoldItalic
- Times-Italic
- Times-Roman
- ZapfDingbats

Custom fonts can also be used in your document. RML supports TrueType and Type 1 fonts. In order to use them, make sure they are on the appropriate path and then register them in the `<docinit>` section at the top of the RML file.

Use the `<registerTTFont>` and `<registerFont>` tags to register them. To use a common set of fonts together as bold, italic etc., you need to put them into a common grouping using the `<registerFontFamily>` tag.

An example of how to use these tags with different font types and styles can be found in the file `rml2pdf/test/test_005_fonts.rml`

### 3.4. Basic text operations - `setFont` and `drawString`

The simplest way to put text on a page is using the `<drawString>` tag. This places the "string" of text on the page at the co-ordinates you give it. The only attributes you can give it are a pair of X and Y co-ordinates. After the tag itself comes the string of text you want put on the page, and then you need the closing `</drawString>` tag.

`DrawString` has a pair of companions. `DrawRightString` and `drawCentredString` both work in the same way, but right justify the string and center it, respectively.

This is how they look in practice:

```xml
<drawString x="523" y="800">
    This is a drawString example
</drawString>

<drawRightString x="523" y="800">
    This is a drawRightString example
</drawRightString>

<drawCentredString x="523" y="800">
    This is a drawCentredString example
</drawCentredString>
```
To set the font that you want a piece of text to be, you need to use the `<setFont>` tag. This has two arguments which are required - you need to give it the name of the font, and the size you want it displayed at.

A `<setFont>` tag looks like this:

```xml
<setFont name="Helvetica-Bold" size="17"/>
```

To use all the `drawString` commands, you need to use a tag called `<pageGraphics>`. This tag appears at the start of a RML document, in the `pageTemplate` section. `pageGraphics` are the graphics that have to do with a whole page (rather than just individual illustrations, as we will see later). `pageGraphics` can be used to provide a background to a page, to place captions or other textual information on a page, or to provide logos or other colorful elements. Whatever you use them for, they are always anchored to a spot on the page - they do not wrap or flow with any text you might put into paragraphs.
4. Basic figures - lines and shapes

4.1. Rect, circle and ellipse

As well as allowing you to place text on the page, pageGraphics also allows you to place shapes and graphics on it.

The basic types of shape that RML allows you to use are:
- rect (rectangle), circle, and ellipse.

A rect needs to have a list of attributes passed to it:
- the co-ordinates for the bottom left hand corner,
- its width and height,

It also has optional fill and stroke attributes, and a round attribute, which tell it if the corners should be rounded off.

The circle needs the following attributes passed to it:
- the x and y co-ordinates of the point where its center should be,
- its radius

If you imagine the ellipse inside a rectangle, the x and y attributes give the co-ordinates for the bottom left hand corner, and the width and height attributes give the co-ordinates for the top right hand corner of the box.

All shapes also have two optional attributes:
- fill, which tells the parser if the shape should be filled in or not, and
- stroke which tells it if the shape should have its outline displayed.

Both these attributes take Boolean values as arguments. You can uses either "1" or "yes" to set them as on, or "0" or "no" to set them as off.

The following example shows various combinations of attributes for each of the basic shapes. Notice how this example starts with the XML definition - you can get away with not using it, but it is still better to make sure it is there.
Figure 3: Output from EXAMPLE 3

EXAMPLE 3

```xml
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM "../rml.dtd">
<document filename="example_3.pdf">
<template>
  <pageTemplate id="main">
    <pageGraphics>
      <!-- set the font and fill colour for the title. -->
      <fill color="red"/>
      <setFont name="Helvetica" size="24"/>
      <!-- Use drawCentredString to place a title on the page -->
      <drawCentredString x="297.5" y="800">Simple Text and Graphics with RML.</drawCentredString>
      <fill color="red"/>
      <!-- look at the output - though a fill color is set, no fill is produced, -->
      <!-- since fill is set to "no" for the circle -->
      <circle x="127.5" y="672.75" radius="1 in" fill="no" stroke="yes"/>
      <fill color="green"/>
      <stroke color="black"/>
      <circle x="297.5" y="672.75" radius="1 in" fill="yes" stroke="no"/>
      <fill color="blue"/>
      <stroke color="black"/>
      <circle x="467.5" y="672.75" radius="1 in" fill="yes" stroke="yes"/>
      <fill color="black"/>
      <setFont name="Helvetica" size="9"/>
      <drawCentredString x="127.5" y="567.5">Circle - with stroke, but no fill.</drawCentredString>
      <drawCentredString x="297.5" y="567.5">Circle - with fill, but no stroke.</drawCentredString>
      <drawCentredString x="467.5" y="567.5">Circle - with both stroke and fill.</drawCentredString>
      <fill color="red"/>
      <ellipse x="77" y="382.25" width="110" height="170" fill="no" stroke="yes"/>
      <fill color="green"/>
      <stroke color="black"/>
      <ellipse x="247" y="382.25" width="110" height="170" fill="yes" stroke="no"/>
      <fill color="blue"/>
      <stroke color="black"/>
      <ellipse x="417" y="382.25" width="110" height="170" fill="yes" stroke="yes"/>
      <fill color="black"/>
      <drawCentredString x="127.5" y="357">Ellipse - with stroke, but no fill.</drawCentredString>
      <drawCentredString x="297.5" y="357">Ellipse - with fill, but no stroke.</drawCentredString>
```
4.2. Fill and stroke

If you look at the example 3, you will see that as well as having fill and stroke attributes for the shapes, there are separate <fill> and <stroke> tags.

Inside the tag for a shape (such as rect), fill and stroke simply tell rml2pdf whether those qualities should be turned on. Should there be a fill, or not? Should there be a stroke, or not? That is why the argument is Boolean - "yes" or "no" (though "1" or "0" are also allowed).

The fill and stroke tags do a different job. The only argument that these tags are allowed is a color. If there are no fill or stroke tags in a document, both the fill and the stroke for all shapes default to black. If you have a fill tag before a shape, it allows you to change the color that that shape is filled with. Similarly, a stroke tag before a shape allows you to set the color that the outline of that shape will be drawn in. If there is no fill or stroke tag in front of a shape, it will be filled and stroked with the most recently defined fill or stroke - or failing that, the default black.

This means that you can use one fill tag to refer to many shapes, while changing the stroke for each of them. Or vice versa.

Another brief example of how the fill and stroke tags look:

```
<fill color="olivedrab"/>
<stroke color="khaki"/>
```

4.3. Lines and lineMode

The other basic drawing element is the line. To draw a simple line, you use the <lines> tag. For each line you want to draw, you pass <lines> two pairs of X-Y co-ordinates - one pair of co-ordinates for the start point of
the line, the other for the end point.

If you want to draw more than one line, you can keep passing `<lines>` more sets of 4 co-ordinates. `<lines>` then draws those other separate lines on the page. The lines in a `<lines>` command are just lumped together in one `<lines>` tag for your convenience. (If you want lines that follow on from each other, look at the "Advanced figures" section later in this manual).

For example, this draws a simple line:

```xml
<lines>
    2.5in 10.5in 3.5in 10.5in
</lines>
```

And this starts with the same line, then draws an extra couple of lines below it:

```xml
<lines>
    2.5in 10.5in 3.5in 10.5in
    2.5in 10.25in 3.5in 10.25in
    2.5in 10in 3.5in 10in
</lines>
```

It doesn't matter how you arrange the sets of co-ordinates, but it helps to keep it human-readable if you keep co-ordinates to do with the same line on the same line of RML. This second example could have been written like this (but it would be much harder to follow):

```xml
<lines>
    2.5in 10.5in 3.5in 10.5in 2.5in 10.25in 3.5in 10.25in 2.5in 10in 3.5in 10in
</lines>
```

One more thing to notice before we move on is that these co-ordinates are separated by spaces. They are *not* separated by commas as you might expect.

As well as just drawing lines, there are a number of attributes you can modify to change the appearance of lines. This is done with the `<lineMode>` tag.

The most obvious attribute to `<lineMode>` is `width`. You can give `<lineMode>` a number for the width attribute to change the line width to that number of points.

```
width = 1
width = 5
width = 10
width = 15
```

*Figure 4: Example of lineMode attribute “width”*

The `join` attribute to `<lineMode>` adjusts how what happens when lines meet. They can either come to a point, or the vertex can be rounded or squared off into a bevelled join. The possible values for join are `round`, `mitered`, or `bevelled`.

The `cap` attribute to `<lineMode>` adjusts how the ends of lines appear. The end of a line can have a square end exactly at the vertex, a square end that is extended so it is over the vertex, or a half circle - a rounded cap. These possible values for cap are `default`, `square` or `round`. 

---

Page 21
Both the `join` and `cap` attributes for `<lineMode>` are only really visible if the line you are applying them to is thick.

Another attribute to `<lineMode>` is `dash`. This allows you to specify if the line is dotted or dashed. You supply it a series of numbers (separated by commas), and it takes them as a pattern for how many pixels the line is on for, and then how many pixels the line is off (i.e. not displayed) for. This can be a simple pattern such as “1,2” (which gives you a plain dotted line) or “5,5” (which makes the lines sections equal with the spaces), or as complex as “1,1,3,3,1,4,4,1” (a complex pattern of dots and dashes).

The following example shows examples of most of the attributes that you can use with `<lines>` and `<lineMode>`. Notice how you can use more that one attribute to `<lineMode>` at the same time.

**EXAMPLE 4**

```
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM "../rml.dtd">
<document filename="example_4.pdf">
  <template>
    <pageTemplate id="main">
      <pageGraphics>
        <setFont name="Helvetica" size="24"/>
        <drawCentredString x="297.5" y="800">Lines in RML.</drawCentredString>
        <!-- notice that each of these "empty" tags are terminated with a slash -->
        <lineMode width="1"/>
        <fills>1in 10.5in 2in 10.5in
          2in 10.5in 1.5in 10in
          1.5in 10in 1.5in 10.75in
        </fills>
        <setFont name="Helvetica" size="9"/>
        <drawCentredString x="1.5 in" y="9.75 in">width = 1</drawCentredString>
        <lineMode width="5"/>
        <fills>2.5in 10.5in 3.5in 10.5in
          3.5in 10.5in 3in 10in
          3in 10in 3in 10.75in
        </fills>
        <setFont name="Helvetica" size="9"/>
        <drawCentredString x="3 in" y="9.75 in">width = 5</drawCentredString>
        <lineMode width="10"/>
        <fills>5in 10.5in 6.5in 10.5in
          6.5in 10.5in 3in 10in
          3in 10in 3in 10.75in
        </fills>
        <setFont name="Helvetica" size="9"/>
        <drawCentredString x="4.5 in" y="9.75 in">width = 10</drawCentredString>
        <lineMode width="15"/>
      </pageGraphics>
    </pageTemplate>
  </template>
</document>
```
5in 6in 4.5in 5.5in
4.5in 5.5in 4.5in 6.25in
</lines>
<drawCentredString x="4.5 in" y="5.25 in">width=10, join=mitered</drawCentredString>
</lines>
<lineMode width="10" join="mitered" miterLimit="20"/>
<lines>5.5in 6in 6.5in 6in
6.5in 6in 6in 5.5in
6in 5.5in 6in 6.25in
</lines>
<drawCentredString x="6 in" y="5.25 in">width=10, join=mitered</drawCentredString>
<drawCentredString x="6 in" y="5.1 in">miterLimit=20</drawCentredString>

<!-- examples for the 'dash' attribute to 'LineMode' -->
<lineMode width="2"/>
<lines>1in 4.5in 2.5in 4.5in
2in 4.5in 1.5in 4in
1.5in 4in 1.5in 4.75in
</lines>
<fill color="black"/>
<setFont name="Helvetica" size="9"/>
<drawCentredString x="1.5 in" y="3.75 in">width=2</drawCentredString>

<!-- options for 'dash' are sequences of numbers -->
<lineMode width="2" dash="5,5"/>
<lines>2.5in 4.5in 3.5in 4.5in
3.5in 4.5in 3in 4in
3in 4in 3in 4.75in
</lines>
<drawCentredString x="3 in" y="3.75 in">width=2, dash=5,5</drawCentredString>
<lineMode width="2" dash="2,10"/>
<lines>4in 4.5in 5in 4.5in
5in 4.5in 4.5in 4in
4.5in 4in 4.5in 4.75in
</lines>
<drawCentredString x="4.5 in" y="3.75 in">width=2, dash=2,10</drawCentredString>
<lineMode width="2" dash="5,5,2,10"/>
<lines>5.5in 4.5in 6.5in 4.5in
6.5in 4.5in 6in 4in
6in 4in 6in 4.75in
</lines>
<drawCentredString x="6 in" y="3.75 in">width=2, dash=5,5,2,10</drawCentredString>
</pageGraphics>
<frame id="first" x1="72" y1="72" width="451" height="698"/>
</pageTemplate>
</template>

<stylesheet>
</stylesheet>
</story>
</story>
</document>
Figure 7: Output from EXAMPLE 4
5. Graphics vs Flowables

Both the basic graphical figures and the basic text operations we have seen so far share some properties. All of them require you to specifically position them at a certain point on a page (or inside a frame) using co-ordinates.

In RML, operations which position elements explicitly on the page using X-Y co-ordinates and other geometric parameters are called "graphics operations" (or just "graphics"). The other major group of tags in RML are the "flowables".

**Flowables** (like paragraphs, spacers, and tables) can appear in a story (or in the `<place>` tag). **Graphics** appear in `<pageGraphics>` and `<illustration>`. These two categories cannot be mixed: flowables are positioned in sequence running down a frame until the frame has no more room and then placed on the next frame (on the next page if necessary); graphics are explicitly positioned by co-ordinates.
6. More about pages and page structures

6.1. More about template and pageTemplate

We have already seen that the `<template>` has to appear at the start of an RML document (after the prolog). This section sets out to explain it more fully.

A `<template>` is the section where the layout of a document is set out - both for the whole document and for individual pages within it.

Up to now, we have just been using `<template>` without any options. But the `<template>` tag has a number of optional attributes that you can use to set settings for the whole document:

- `pageSize` sets the size of the page. This takes a pair of numbers for the width and the height of the page. If you don't give it any numbers, it defaults to A4 (the international standard page size which differs from the American standard page size of letter, but is a standard in other places such as the UK). While this is a sensible default, it's usually best to explicitly specify a size. Common sizes are (21cm, 29.7cm) or (595, 842) for A4, (8.5in, 11in) for letter, and (8.5in, 17in) for legal.

- `rotation` sets the angular orientation of the page. This is a float or integer number that should be a multiple of 90. The default value is zero.

- `leftMargin` and `rightMargin` set the horizontal margins for the page. `topMargin` and `bottomMargin` set the vertical margins for the page.

You can also set the title of the document with the `title` attribute (which defaults to '(untitled)') and the author with the `author` attribute (which defaults to '(unauthored)').

There are also the optional `showBoundary` and `allowSplitting` attributes, which can both be set to "0" or "1" (or "true" and "false"). The `showBoundary` attribute is off by default, but when it is set to `true`, it shows a black border around any frames on the page.

A `<template>` allows you to set options for the whole document. The `<pageTemplate>` tag allows you to set options for individual pages. You can have more than one `<pageTemplate>` inside the template section. This allows you to have different pageTemplates for each page that requires a different structure. For example, the title page of a report could have a number of graphics on it while the rest of the pages are more text-oriented.

Each `<pageTemplate>` tag must have the mandatory attribute `id`. This gives the template a name, and allows both rml2pdf and you to refer to it by name.

The `<pageTemplate>` tag also allows you to override the `rotation` and `pageSize` set by the `<template>` tag.

As well as these attributes, you can put any number of `<pageGraphics>` into a `<pageTemplate>` (<`pageGraphics`> are the containers for the `<drawString>` and shape-drawing commands we saw earlier).

In practice, you may have two `<pageGraphics>` sections inside a `<pageTemplate>`. The way this is interpreted by RML2PDF is that the first one is carried out before the contents of the story for that page, and the second one is carried out after the story. This may be of use when you need some elements to overlap others, and particularly useful when you are using the `<includePdfPages>` tag. IncludePdfPages places a number of pages imported from another PDF file into your document, placing them over the content you already have (including any header and footers you have designed). This may mean it obscures headers, footers or something else you need on every page. The way around this is to place your headers and footers in a second pageGraphics section, which ensures that it will appear over anything in your story. Provided you have sensibly defined frames it won't appear over the main content of your page, but it will appear over the top of your included PDFs allow-
ing you to have the same look-and-feel for these pages as you do for the rest of your document.

(See section 8.8 ("Integrating with PageCatcher: catchForms, doForm and includePdfPages") for more info on the <includePdfPages> tag.)

6.2. Frame and nextFrame

As well as containing <pageGraphics>, each <pageTemplate> can also contain frames. These frames can split the page into more than one region. For each frame in a <pageTemplate>, you must supply an id, the X and Y co-ordinates of the bottom left hand corner, as well as the width and height of the frame. You can have one frame in a page, or use two or more to split it into a multi-column layout. Frames really come into their own when you use paragraphs and flowables (see the section on "Advanced text" below).

This is how it looks in practice:

```xml
<frame id="main" x1="4in" y1="2in" width="3in" height="7in"/>
```

(When you are using text in <para></para> tags, you can use the <nextFrame/> tag to force it into the next frame on the page. Look at the section on "Advanced text" later in this document for more details on this). An additional attribute overlapAttachedSpace can be set to 0 or 1 to force the frame to overlap space that is implicitly attached to flowables by their styles. See section 6.5 on styles. The default value for this attribute is set using the site wide configuration for reportlab (in reportlab/rl_config.py).

6.3. condPageBreak: conditional page breaks

The <condPageBreak/> is a "CONDitional Page Break". To use it, you give it a height in any units that RML can handle. It then compares this height with the remaining available space on a page. If the space is sufficient, then the next elements are placed on the current page, but if there is less space than the height you have given it anything following the <condPageBreak/> tag is continued on the next page.

That is what happens on pages with only one frame. On pages that have multiple frames, this tag acts as a conditional frame break. If the space in the current frame isn't enough, it will break and place what follows in the next frame rather than on the next page. The tag and its syntax still remain the same.

This tag is particularly useful with large tables, where you want the whole table to be presented on one page rather than split between two. It can also be used where you have a collection of images, and you want them all to be on the same page.

The <condPageBreak/> has only one attribute - the mandatory one of height.

Examples:

```xml
<condPageBreak height="1in"/>
<condPageBreak height="72"/>
```

6.4. storyPlace: out of band flowables

The <storyPlace> container is a "flowable story that's placed". This allows for dynamically specified frames to be constructed in the story. This tag is like having an <illustration> & <place> combination although you cannot separate an illustration from its frame as you can with <storyPlace>.

<storyPlace> takes 4 required attributes and one optional one. x, and y are the x and y co-ordinates for where you want the flowables placed. width and height are the width and height of the flowable. Finally the origin can be one of page|frame|local. If not specified local is assumed. The origin attribute speci-
fies where the x and y attributes are based.

Examples:

```xml
<storyPlace x="0" y="0" width="18cm" height="1cm" origin="page">
  <para>This is right at the bottom of the page</para>
</storyPlace>
<storyPlace x="0" y="0" width="18cm" height="1cm" origin="frame">
  <para>This is right at the bottom of the current frame</para>
</storyPlace>
<storyPlace x="0" y="0" width="18cm" height="1cm" origin="local">
  <para>This is right at the current frame position!</para>
</storyPlace>
```

### 6.5. pto: Please Turn Over Control

The `pto` tag is a flowable container that holds an arbitrary number of other flowables. The first two may be special `pto_trailer` or `pto_header` tags each of which may contain arbitrary flowables. The idea is that the trailer flowables are issued at the bottom of the page whenever the main container flowables split; the header flowables appear at the top of the next frame.

```xml
<pto>
  <pto_trailer>
    <para textColor="blue" style="pto">See you on next frame</para>
  </pto_trailer>
  <pto_header>
    <para textColor="blue" style="pto">back from the previous frame</para>
  </pto_header>
  <para style="h1">A header</para>
  <para style="bt">Many vast star fields in the plane of our Milky Way Galaxy are rich in clouds of dust, and gas. First and foremost, visible in the above picture are millions of stars, many of which are similar to our Sun. Next huge filaments of dark interstellar dust run across the image and block the light from millions of more stars yet further across our Galaxy.</para>
</pto>
```

### 6.6. keepInFrame fixed space control

The `keepInFrame` tag is a flowable container that holds an arbitrary number of other flowables. The intention is that the container controls the space allocated to the inner flowables. Errors will be caused by attempts to use `<nextFrame/>` and similar tags inside the `keepInFrame` container.

The `keepInFrame` tag takes several attributes. `maxWidth` is the maximum width. If zero then the available width will be used. `maxHeight` is the maximum height. If zero then the available height will be used. `frame` if specified this should be the name or index of the frame in which the contents should be drawn. The `framechange` take place before widths etc are evaluated. `mergeSpace` if `1` then adjacent pre and post space for the content elements will be merged. `onOverflow` this specifies the action to be taken if the contents is too large. Allowed values are `error` ie raise an error, `overflow` just scrawl all over the page, `shrink` shrink the contents to fit the allowed space, & `overflow` truncate the contents at the borders of the allowed space.
The example below shows how to cram star fields into a one inch square.

```xml
<keepInFrame maxWidth="72" maxHeight="72">
  <para style="h1">A header</para>
  <para style="bt">
    Many vast star fields in the plane of our Milky Way Galaxy
    are rich in clouds of dust, and gas. First and foremost,
    visible in the above picture are millions of stars, many
    of which are similar to our Sun. Next huge filaments of
dark interstellar dust run across the image and block the
light from millions of more stars yet further across our Galaxy.
  </para>
</keepInFrame>
```

### 6.7. `imageAndFlowables` tag

The `<imageAndFlowables>` tag allows flowables to flow around an image. Errors will be caused by attempts to use `<nextFrame/>` and similar tags inside the `<imageAndFlowables>` container.

The `<imageAndFlowables>` tag takes several attributes. `imageName` the name of the image file or path. `imageWidth` the width of the image; using 0 will cause the pixel size in points to be used. `imageHeight` the height of the image; using 0 will cause the pixel size in points to be used. `imageMask` a transparency colour or the word "auto"; this only works for image types that support transparency. `imageLeftPadding` space to be used on the left of the image. `imageRightPadding` space to be used on the right of the image. `imageTopPadding` space to be used on the top of the image. `imageBottomPadding` space to be used on the bottom of the image. `imageSide` which side the image should go on; "left" or "right".

Example:

```xml
<imageAndFlowables imageName="../doc/images/replogo.gif" imageWidth="141" imageHeight="90" imageSide="left">
  <para style="h1">Test imageAndFlowables tag with paras</para>
  <para style="style1">We should have an image on the <b>right</b> side of the paragraphs here.</para>
</imageAndFlowables>
```

### 6.8. More about stylesheets

Just like in a word processor, RML allows you to define a stylesheet at the start of your document, and then apply it to paragraphs later on. This means that you can define a complicated mixture of settings that you want to apply to paragraphs, only define it in one place, and refer to it with a simple name at the start of each paragraph...
rather than having to type or cut-and-paste large blocks of text over and over for each paragraph.

Each stylesheet starts with the `<stylesheet>` tag. There may then be an optional initialisation section where aliases can be set (bounded by the pair of tags `<initialize></initialize>`). After that come a number of `<paraStyle>` tags - each one defining a style that you want to use for paragraphs. The `<paraStyle>` tag must have an attribute `name`, and then may have as many optional attributes as you want, each one setting one feature of the appearance of a paragraph.

Each one of these `<paraStyle>` tags is an empty element (i.e. it is closed with a "/>") rather than a separate closing tag, but you might want to indent the tag so that each of the options is on a separate line. This makes it easier to see what each style is defining (see the example below for how this looks).

One attribute for `<paraStyle>` that isn't the same as those used by `<para>` is the `parent` attribute. Once you have defined a style using a `<paraStyle>` tag, you can use those settings as a basis for other styles. `parent` allows one style to inherit from another.

The other attribute that isn't shared by the `<para>` tag is `backColor`. As you can probably guess, this attribute sets a background color for the paragraph it is describing.

The following optional attributes for `<paraStyle>` are the same as those for the `<para>` tag - you can find more description of them in the "Advanced text" section below: `fontName`, `fontSize`, `leading`, `leftIndent`, `rightIndent`, `firstLineIndent`, `alignment`, `spaceBefore`, `spaceAfter`, `bulletFontName`, `bulletFontSize`, `bulletIndent`, `textColor`.

Here is an example of how the `<stylesheet>` tag might look in use:

```xml
<stylesheet>
  <initialize>
    <alias id="style.normal" value="style.Normal"/>
  </initialize>

  <paraStyle name="h1"
    fontName="Courier-Bold"
    fontSize="12"
    spaceBefore="0.5 cm"/>

  <paraStyle name="style1"
    fontName="Courier"
    fontSize="10"/>

  <paraStyle name="style2"
    parent="style1"
    leftIndent="1in"/>

  <paraStyle name="style7"
    parent="style1"
    leading="15"
    leftIndent="1in"
    rightIndent="1in"/>

</stylesheet>
```
stylesheets also allow you to define styles for other tags - you can define styles for blockTables with the 
<blockTableStyle> tag, or the various form creation elements (checkBoxes, letterBoxes and text-
Boxes) with the boxStyle tag. Refer to the sections on blockTables and Form Field Tags later in this doc-
ument for details on how to use these.
7. Advanced text

7.1. Title

The `<title>` tag sets the title for a document, or a section of a document, and displays it on the page. By default, this is set in a larger typeface than the body text (in a similar way that headers are). You can change the way a title is set by setting a style called `style.Title` (in the stylesheet section of your document).

[Note: This tag does not affect what is displayed in the "title bar" at the top of a document.]

Example:

```xml
<stylesheet>
  <paraStyle name="style.Title"
      fontName="Courier-Bold"
      fontSize="36"
      leading="44"/>
</stylesheet>

<story>
  <title>This is the Title</title>
  <para>
    And it should be set in 36 pt Courier Bold.
  </para>
</story>
```

7.2. Headings -- h1, h2, h3

Headings are also handled in the same way as in HTML. The most important heading level has its text enclosed by `<h1>` and `</h1>` tags, and less important sub-headings use the `<h2>` and `<h3>` tags in the same way.

7.3. Paragraphs and paragraph styles

As well as explicitly placing a piece of text into a certain position on a page using the `drawString` commands, RML also allows you to use paragraphs of text. Paragraphs are `flowables`. This means that you don't need to tell RML exactly where every line is going to go on the page - you let rml2pdf worry about that.

To do this you place your text inside the `story` section of an RML document, and use the `<para>` and `</para>` tags to tell the parser where each paragraph starts and ends.

As well as delineating where paragraphs begin and end, the `<para>` tag can also have a number of optional attributes:

`style:`
If you have set up a style in the stylesheet section of a document, you can refer to them by name by using the `style` attribute. For example, if you have defined a style called `Normal`, you can have your paragraph appear in that style by using `<para style="Normal">`.

`alignment:`
How the text is aligned within the paragraph. It can be `LEFT`, `RIGHT`, `CENTER` (or `CENTRE`) or `JUSTIFY`.

`fontName, fontSize:`
fontName and fontSize set the name and size of the font that you want this paragraph displayed in. (This can often be better done using the <paraStyle> tag inside a <stylesheet>, and then using the <style> tag to apply it to that paragraph). Example: <para fontName="Helvetica" fontSize="12">

leading:
leading is used is used to alter the space between lines. In RML, it is expressed as the height of a line PLUS the space between lines. So if you are using 10 point font, a leading of 15 will give you a space between lines of 5 points. If you use a number that is smaller than the size of font you are using, the lines will overlap.

leftIndent, rightIndent:
leftIndent and rightIndent apply space to the left or right of a paragraph which is in addition to any margin you have set.

firstLineIndent:
firstLineIndent is used when you want your paragraph to have an additional indent on the first line - on top of anything set with leftIndent.

spaceBefore, spaceAfter:
spaceBefore and spaceAfter, as you would expect, set the spacing before a paragraph or after it.

textColor:
This sets the color to be used in displaying a paragraph.

bulletText, bulletColor, bulletFontName, bulletFontSize, bulletIndent:
These are all used to set the characteristics for any bullets to be used in the paragraph.

Inside the story, you can also do a number of things that you can't do with the drawString commands. For a start, you can use bold, italics and underlining. If you are familiar with HTML, you will recognize these tags - <i> and </i> start and stop italics, <b> and </b> start and stop the text being set as bold, and <u> and </u> start and stop underlining.

7.4. The font tag
You can also explicitly set the font using the <font> tag. This has the optional attributes of face, color, and size which are all pretty self-explanatory. You need to use a </font> tag to close this before the end of the paragraph. Example:

<font face="Courier" color="crimson">This is courier in crimson!</font>

That example produces this line of text:
This is courier in crimson!

7.5. Superscripts and subscripts
Another thing you can do inside the story is using superscripts and subscripts. You do this with the <super></super> and <sub></sub> tags. (Superscript is where the text is raised up on the line such as in the mathematical symbol for squared or cubed, and subscript is where it is lowered relative to the rest of the line in the same way). The <super> tag can also be called <sup>. Thses tags have optional attributes rise to set the baseline shift (negatively for <sub>) and size which sets the font size to use in the tag. The default rise is 50% of the font size and the default size is the existing font size - min(2,20% of existing font size). Example:

<para>
  <sub>This is subscript.</sub>
  This is normal text.
  <super>This is superscript.</super>
</para>
That example produces this:

This is subscript. This is normal text. This is superscript.

whereas this example:

```xml
<para>
    <sub size="6" rise="5">This is subscript.</sub>
    This is normal text.
    <super size="6" rise="5">This is superscript.</super>
</para>
```

produces this:

This is subscript. This is normal text. This is superscript.

7.6. Lists

RML supports ordered and unordered lists, using the tags `<ol>`, `<ul>` and `<li>`. They work in a similar way to their HTML equivalents. A list item can be any normal flowable element but there can be only one such item within a pair of list item tags. Lists can be nested.

**WARNING:** The contents of a list are flowable objects, and the list itself does not know what font sizes or spacing you will use in the enclosed paragraphs. Therefore, if you want to get normal typography, it’s very important to define a `<listStyle>` with font names, size and spacing matching that of the `<paraStyle>` you use for the enclosed text.

You should also be aware that RML’s `<para>` tag already has a flexible feature named the ‘bullet’ which can provide bulleted, numbered and definition lists which match the corresponding text. In general lists should only be used when you are transforming in a mapping from HTML, or when you need to place arbitrary flowables such as tables or images in the body of a list.

Lists and list items can be styled using tag attributes or with `<listStyle>` tags in the stylesheet section. See the rml.dtd for the full list of attributes on the `<ul>`, `<ol>` and `<li>` tags using LIST_MAIN_ATTRS.

In ordered lists, you can use the following types of enumeration in the `bulletType` or `start` attributes:

- `T`: Roman numerals (capitals)
- `I`: Roman numerals (lower case)
- `1`: Arabic numerals
- `A`: Capital letters
- `a`: Lowercase letters

For unordered lists, `bulletType` must be set to ‘bullet’

Unordered lists can use bullet types of the following shapes by setting the 'start' attribute in `<ul>` or the 'value' attribute in `<li>` tags:

- bulletchar
- square
- disc
- diamond
- diamondwx
- circle
blackstar
squarers
arrowhead

Alternatively any non-whitespace character can be used as a bullet.

As a final possibility blank separated strings of the possible starts can be used to indicated that automatic depth changes should be attempted.

The size, colour and position (indenting, space before/after etc.) of bullets and enumerations can be adjusted with the relevant tag attributes. List item attributes override the attributes on <ol> or <ul> tags.

Definition lists are not yet implemented.

A simple example of nested ordered/unordered lists:

```rml
<story>
  <ol bulletColor="red" bulletFontName="Times-Roman">
    <li bulletColor="blue" bulletFontName="Helvetica">
      <para>
        Welcome to RML 1
      </para>
    </li>
    <li>
      <ul bulletColor="red" bulletFontName="Times-Roman" bulletFontSize="5" rightIndent="10">
        <li bulletColor="blue" bulletFontName="Helvetica">
          <para>
            unordered 1
          </para>
        </li>
        <li>
          <para>
            unordered 2
          </para>
        </li>
      </ul>
    </li>
  </ol>
</story>
```

For more examples of how to use lists see ’test_046_lists.rml’ in ’/rlextra/rml2pdf/test/’.

7.7. Using multiple frames

If you have split your page into more than one frame, you can flow text between frames. To do this you use the <nextFrame/> tag. This is an "empty" or "singleton" tag - it doesn't take any content. Put in <nextFrame/> and your text will continue into the next frame. It should appear outside your paragraphs - between one </para> and the next <para> tag. An optional name attribute can be used to specify the name or index of the frame which you wish to switch to.

You can control the automatic switch of frames by using the <setNextFrame/> tag. The required name attribute can be used to specify the name or index of the frame which you wish to switch to. The <setNextFrame/> tag is an "empty" or "singleton" tag - it doesn't take any content. Put in <setNextFrame name="F5"/> and your text will flow into the frame specified. It should appear outside your paragraphs - between one </para> and the next <para> tag.
If you have defined more than one kind of template (by using `<pageTemplate>` in the template section at the head of the RML document), you can also force RML into using a new template for the next page. You do this by using the `<setNextTemplate>` tag. This tag has only one attribute - the mandatory one of `name`, which tells RML which template it should use.

In practice, you would usually set the next template and then use a `nextFrame`:

```xml
<setNextTemplate name="yetAnotherTemplate"/>
<nextFrame/>
```

### 7.8. Preformatted text -- pre and xpre

One tag that is also a flowable, but that can’t be used inside the `<para>` tags is `<pre>`. Just as in HTML, the `<pre>` tag denotes pre-formatted text. It displays text exactly as you typed it, with the line breaks exactly where you put them and no line-wrapping. If you want to keep any formatting in your text (such as tabs and extra whitespace), enclose it in `<pre>` tags rather than `<para>` tags.

You can also pass a style to the `<pre>` tag. If you don’t use the optional style attribute, anything between the `<pre>` tag and the `</pre>` tag will appear in the default style for pre-formatted text. This uses a fixed width "typewriter" font (such as courier), and is useful for things such as program listings, but may not be what you want for your quotation or whatever. If you have already defined a style (in the stylesheet section of your RML document), then you can make the `<pre>` tag use this for your pre-formatted text.

Example:

```xml
<pre style="myStyle">
  this is pre-formatted text.
</pre>
```

The `xpre` is similar to the `pre` tag in that it preserves line breaks where they are placed in the text, but `xpre` also permits paragraph annotations such as bold face and italics and font changes. For example, the following mark-up

```xml
<xpre>
  this is an <i>xpre</i> example
  <font color="red">including red text!</font>
</xpre>
```

generates the following text

```
this is an xpre example
including red text!
```

### 7.9. Greek letters

The `<greek>` tag is used for producing Greek letters in RML. This is of most use for equations and formulae.

Example:

In physics, Planck’s formula for black body radiation can be expressed as:

$$R\lambda=(c/4) \left(8\pi\lambda^4 \right) \left( \frac{hc}{\lambda} \right) \frac{1}{e^{hc/\lambda kT} - 1}$$
In RML, this is expressed as:

\[ R = \left(\frac{c}{4}\right) \left(\frac{8p}{l^4}\right) \left[ \frac{hc}{l} e^{-\frac{hc}{kT}} \right] \]

For a table of the Greek letters used by the \texttt{<greek>} tag and their representations in RML, look in Appendix C at the end of this manual.

This next example shows features from several of the commands described in the previous sections; such as the use of frames, the options to the \texttt{template} tag, stylesheets, and so on. See the next section for information on using the \texttt{<name>} and \texttt{<getName>} tags.

**EXAMPLE 5**

```xml
<template>
  <pageTemplate id="main">
    <pageGraphics/>
    <frame id="titleBox" x1="2.5cm" y1="27.7cm" width="16cm" height="1cm"/>
    <frame id="columnOne" x1="2.5cm" y1="2.5cm" width="7.5cm" height="24.7cm"/>
    <frame id="columnTwo" x1="11cm" y1="2.5cm" width="7.5cm" height="24.7cm"/>
  </pageTemplate>
</template>

<stylesheet>
  <initialize>
    <name id="FileTitle" value="Example 5 - templates and pageTemplates"/>
    <name id="ColumnOneHeader" value="This is Column One"/>
    <name id="ColumnTwoHeader" value="This is Column Two"/>
  </initialize>
  <paraStyle name="titleBox" fontName="Helvetica-Bold" fontSize="18" spaceBefore = "0.4 cm" alignment = "CENTER"/>
  <paraStyle name="body" fontName="Helvetica" fontSize="10" leftIndent = "5" spaceAfter = "5"/>
</stylesheet>

<story>
  <para style = "titleBox">
    <getName id="FileTitle"/>
  </para>
  <para>
    This is the contents for \texttt{<b>column one</b>}.\n  </para>
  <para>
    It uses the default style for paragraph.\n  </para>
</story>
```

**EXAMPLE 4**
Does it come out OK?
</para>
</para>
There now follows some random text to see how these paragraphs look with longer content:

</story>
</document>
7.10. Asian Fonts

RML supports all of Adobe's Asian Font Packs. You can display text in Japanese, Traditional and Simplified Chinese and Korean using two different techniques.

The most robust technique is to include the standard Asian fonts Adobe specifies for use with Acrobat Reader. These will already be installed on the end user's machine if they have a localized copy of Acrobat Reader, or may be downloaded in the free "Asian Font Packs" from Adobe's site. In these cases there is no need to embed any fonts or to have any special software on the server. The first stage is to declare the fonts you need in the optional 'docinit' tag at the beginning of the document as follows:

```xml
<document filename="test_015_japanese.pdf">
  <docinit>
    <registerCidFont faceName="HeiseiMin-W3"/>
  </docinit>
  etc.
</template ...>
```

**Note:** The `encName` attribute of `registerCidFont` is deprecated: you should not use it with new documents.

You may then declare paragraph styles, use string-drawing operations or blockTable fonts referring to the font you have defined:
The test directory includes a file `<samp>test_015_japanese.rml</samp>` containing a working simplified example in Japanese.

**Warning:** You will need to have a number of CMap files available on your system. These are files provided by Adobe which contain information on the encodings of all the glyphs in the font. RML2PDF looks for these in locations defined in the `CMapSearchPath` variable in the file `reportlab/rl_config.py`, which knows where to find Acrobat Reader on most Windows and Unix systems. If you wish to use Asian fonts on another system, you can copy these files (which may be redistributed freely) from a machine with Acrobat Reader on to your server.

*Editor's note at 28/12/2002 - there is a great deal of information on fonts which needs adding to this manual including embedded Type 1 fonts and encodings and use of embedded subsetted TrueType fonts*

### 7.11. Paragraph Hyphenation

Hyphenation functionality (requires Pyphen package installed) - Pyphen is a pure Python module to hyphenate text using included or external Hunspell hyphenation dictionaries.

**Usage** - Set the `hyphenationLang` attribute in the `paraStyle` and the content will be split according to the language used.

You can also exclude any word or part of a sentence from hyphenation by opening and closing a `nobr` tag around the content.

If the pyphen python module is installed attribute `hyphenationLang` controls which language will be used to hyphenate words without explicit embedded hyphens.

If `embeddedHyphenation` is set then attempts will be made to split words with embedded hyphens. Attribute `uriWasteReduce` controls how we attempt to split long uri's. It is the fraction of a line that we regard as too much waste. The default in module `reportlab.rl_settings` is 0.5 which means that we will try and split a word that looks like a uri if we would waste at least half of the line.

Currently the hyphenation and uri splitting are turned off by default. You need to modify the default settings by using the file `~/.rl_settings` or adding a module `reportlab_settings.py` to the python path.

Suitable values are

```python
hyphenationLanguage='en_GB'
embeddedHyphenation=1
uriWasteReduce=0.3
```

More examples here: `test_001_hello.rml` `test_001_hello.pdf`
Part II - Advanced Features

8. Miscellaneous useful features

8.1. pageNumber

As you’d expect from the name, this tag adds page numbers to your document. This has nothing tricky to remember - all you have to do is put the a `<pageNumber/>` tag where you want the page number to appear.

8.2. name, namedString and getName

The `<name>` and `<namedString>` tags allow you to set a variable as you would in a programming language. You can then retrieve this to put in another place by using the `<getName>` tag. You can do this as many or as few times as you need - so it is handy for things like headers and footers, or for items that you see changing many times over the life of your document such as version or revision numbers. If you set them using a `<name>` tag, you only have to revise them in one place every time they change, rather than having to plough through the document changing them manually in each location and inevitably missing one.

`<name>` has three attributes: `id` and `value` are required, but `type` is optional.

`<namedString>` has five main attributes: `id` is required as the name of the variable. This tag is not self closing and the value to be assigned should be between `<namedString>` and `</namedString>`. The `new` attribute may be set to "1" to indicate that the definition should happen only on the first time this variable is seen. The `discard` attribute may be set to "1" to indicate that the definition should happen immediately and not at render time and the value is discarded. The `indexName` attribute may be set to the name of another variable which should be used as an index into the main variable where the value should be stored.

`<getName>` only has three attributes the first `id` is required so that it knows which name to "yank". The `default` attribute may be used to supply a default value (in case the variable is not yet defined). Finally the `indexName` attribute may be used to specify an index name that is to be looked up to index into the id variable allowing complex programming see https://www.reportlab.com/examples/rml/test/test_052_pagenum.rml.

In practice, it would look something like this example:

```xml
<stylesheet>
  <initialize>
    <name id="YourVariableName" value="Type anything you want between these quotes..."/>
    <namedString id="x">0</namedString>
    <namedString id="anothervariable" indexName="x">value of anothervariable</namedString>
  </initialize>
</stylesheet>

<story>
  <para>
    <b><getName id="YourVariableName"/></b>
    <b><getName id="anothervariable" indexName="x"/></b>
  </para>
</story>
```

You can also use the `<name>` tag inside the story of a document. In this case, as well as setting the value for the variable, it is also displayed on the page (i.e. the name has a "textual value").
8.3. Seq, seqReset, seqChain and SeqFormat

The "seq" in <seq>, <seqDefault> and <seqReset> stands for sequence. These tags are all used for paragraph numbering (or indeed anything that requires numbering items in a sequence, such as list items or figures and illustrations).

This is how they look in use:

```
<seq/>
<seqDefault id="myID"/>
<seqReset/> or <seqReset id="myID"/>
<seqChain order="id0 id1 id2...idn"/>
<seqFormat id="myID" value="i"/>
```

Each time you call <seq />, its value is automatically incremented.

With <seqReset />, the id is an optional attribute. However, it is still best to use it to save confusion.

The <seqChain order="id0 id1 id2"/> tag is used to make multi sequence use easier. When sequence id0 is changed sequence id1 is reset; likewise when sequence id1 is changed sequence id2 is reset and so on for the identifiers in the order attribute.

The tag <seqFormat id="myID" value="i"/> is used to associate a numbering format to myID. The allowed values for the value attribute are given in the table below.

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Decimal</td>
</tr>
<tr>
<td>i</td>
<td>Lowercase Roman</td>
</tr>
<tr>
<td>I</td>
<td>Uppercase Roman</td>
</tr>
<tr>
<td>a</td>
<td>Lowercase Alphabetic</td>
</tr>
<tr>
<td>A</td>
<td>Uppercase Alphabetic</td>
</tr>
</tbody>
</table>

Here is an example that shows <seq />, <seqReset> and <seqDefault> in use:

```
<xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM ".../rml.dtd">
<document filename="example_6.pdf">
<template>
  <pageTemplate id="main">
    <frame id="first" x1="72" y1="72" width="451" height="698"/>
  </pageTemplate>
</template>
<stylesheet>
</stylesheet>
<story>
  <h1>seq in seq, seqDefault and seqReset</h1>
  <para>copied: <seq id="spam" />, <seq id="spam" />, <seq id="spam" "/>.
  Reset<seqReset id="spam" "/>. <seq id="spam" "/>, <seq id="spam" "/>, <seq id="spam" "/>, .</para>
  <h2>simple use of seq</h2>
  <para>First seq: <seq/>
  </para>
  <para>Second seq: <seq>
  </para>
  <para>
  <spacer length="6"/>
  ```
We have just done a \texttt{seqReset}/

First seq after \texttt{seqReset}: \texttt{seq}/

second seq after \texttt{seqReset}: \texttt{seq}/

If you are going to use multiple \texttt{seq} tags, you need to use the \texttt{*id*} attribute.

\texttt{seqDefault id="test"}/

We have just done a \texttt{seqDefault id="test"}/

First seq: \texttt{seq id="test"}/

Second seq: \texttt{seq id="test"}/

First seq for \texttt{testOne}: \texttt{seq id="testOne"}/

Second seq for \texttt{testOne}: \texttt{seq id="testOne"}/

First seq for \texttt{testTwo}: \texttt{seq id="testTwo"}/

Second seq for \texttt{testTwo}: \texttt{seq id="testTwo"}/

Notice how resetting \texttt{testOne} doesn’t affect \texttt{testTwo} at all.

Better use of \texttt{seq}/

Using two \texttt{seq} independently/
seq in seq, seqDefault and seqReset

copied: 1, 2, 3. Reset. 1, 2, 3.

**simple use of seq**
First seq: 1
Second seq: 2
We have just done a `<seqReset/>`
First seq after seqReset: 1
second seq after seqReset: 2
If you are going to use multiple seq tags, you need to use the “id” attribute.

**Better use of seq**
We have just done a `<seqDefault id="test"/>`
We have just done a `<seqReset id="test"/>`
First seq: 1
Second seq: 2
We have just done a `<seqReset id="test"/>`
First seq after seqReset: 1
second seq after seqReset: 2

**Using two seqs independently**
We have just done a `<seqReset id="testOne"/>`
We have just done a `<seqReset id="testTwo"/>`
First seq for testOne: 1
Second seq for testOne: 2
First seq for testTwo: 1
Second seq for testTwo: 2
We have just done a `<seqReset id="testOne"/>`
First seq after seqReset for testOne: 1
second seq after seqReset for testOne: 2
First seq after seqReset for testTwo: 3
second seq after seqReset for testTwo: 4

Notice how resetting testOne doesn’t affect testTwo at all.

*Figure 9: The output from EXAMPLE 6*

One more sophisticated use for using these tags is for multiple page counters. If you have a document where you need different sections numbered separately from the main body of a document (perhaps for introductory matter such as the contents and preface of a book), this can be done with a named seq tag.

The page counter as used by the pageNumber tag is a ‘unique value’ which depends on the actual physical number of pages. If rather than using a pageNumber tag, you instead use something like `<seq id="pageCounter"/>`, you have the ability to use `<seqReset id="pageCounter"/>` in between sections so that each chapter has pages numbered from the start of that chapter rather than the start of the document. If you use a different template for each chapter, this can then give you page numbers in the format “1-12”
rather than just "12" (where you are on page 12 of the document, which is page 12 of chapter 1).

8.4. Entities
In example 6, we saw our first use of entities. In RML, you can't use the characters "<", "," or "&" inside any display elements such as drawString or para. If you do, rml2pdf will assume that they are tags and attempt to interpret them. Since they won't be valid RML tags, you will just end-up getting an error message along the lines of "Error: Start tag for undeclared element <YourNonValidTag>".

To get around this, you should use "entities".

When you need to use "<", replace it with "&lt;", when you need to use ">", replace it with "&gt;", and when you need to use "&", replace it with "& amp;".

### 8.5. Aliases

Aliases allow you to assign more than one name to a paragraph style.

The alias tag has two required attributes - id and value.

Example:

```
<alias id="alreadyDefinedStyleName" value="myNewStyleName"/>
```

This can be useful in a number of ways.

You can give a more descriptive name to a style. So you can define a number of paragraph styles called things like "ItalicBold" or "DesignerOneParagraphStyleTwo" in the stylesheet for your document. You can then assign aliases to these styles using names that describe the role they fill in your document such as "pictureCaption", "abstract", "acknowledgement" and so on.

If at any point you decide to change the style for that kind of paragraph, you can then change it in one alias rather than in every individual paragraph that uses that style.

### 8.6. CDATA -- unparsed character data

CDATA is a standard XML tag which indicates to the parser (in this case rml2pdf) to ignore anything inside the CDATA section. It shouldn't parse it or process it in any way - just display it.

A CDATA section is started with the characters "<! [CDATA [" and is closed off with the characters "] ] >". It can appear inside any flowable - though it is most useful inside a <pre> tag.

CDATA may be useful in places where you have large quantities of "<" and ">" characters that you want to display in your PDF, and that you would rather not have to convert them all to "&lt;" and "&gt;" entities. Quoting sections of RML, XML, or HTML code is an example of a good place to use CDATA - if you needed to revise the code example at a later date, you would have to convert the characters in every tag into entities. CDATA saves you having to do this.

However, you should only use CDATA when necessary. If you are using other XML tools, they will also ignore anything inside a CDATA section.

Example:
8.7. Plug-ins: plugInGraphic and plugInFlowable

Both plugInGraphics and plugInFlowables allow you to use objects from outside your RML document.

**plugInGraphic**

A plugInGraphic identifies a function (callable) in a module which takes a canvas and a data string as arguments and presumably draws something on the canvas using information in the data string.

Example:

```plaintext
<plugInGraphic module="mymodule" function="myfunction">data string</plugInGraphic>
```

when executed results in effectively the following execution sequence:

```python
import mymodule
mymodule.myfunction(canvas, "data string")
```

using the current canvas object.

<PlugInGraphic> has two mandatory attributes: module and function. It is used in the <pageGraphics> section of your document.

**plugInFlowable**

A plugInFlowable identifies a function (callable) in a module which takes a canvas data string as an argument and returns a flowable object:

Example:

```plaintext
<plugInFlowable module="mymodule" function="myfunction">data string</plugInFlowable>
```

when executed results in effectively the execution sequence:

```python
import mymodule
flowable=mymodule.myfunction("data string")
story.append(flowable)
```

using the current canvas object.

plugInFlowable has two mandatory attributes: module and function. It is also used in the <pageGraphics> section of your document.

8.8. Integrating with PageCatcher: catchForms, doForm and includePdfPages

You can use our product PageCatcher to capture individual pages from an external PDF file (e.g. application forms, government forms, annual reports and so on). Extracting the required pages with PageCatcher will most
often be a one-off design-time step. Once PageCatcher has extracted a page, it archives it in a data file as formatted form data. (The default name for this file is "storage.data").

If you have full production versions of both RML2PDF and PageCatcher you can use the <catchForms> tag to import all forms from a PageCatcher storage file for use in your RML document.

Example:
This example takes the form called PF0 (a page "caught" by PageCatcher and stored in the file storage.data) and draws it into your document as a page backdrop.

```xml
<pageDrawing>
  <catchForms storageFile="storage.data"/>
  <doForm name="PF0"/>
</pageDrawing>
```

The <catchForms> tag is a drawing operation, and can occur anywhere in your RML document where a <doForm> tag can occur. (For example, you can use a <catchForms> inside the flow of a story by using it inside an <illustration>). The <catchForms> tag has one mandatory argument (storageFile) which gives the name of the PageCatcher storage file to extract the form from.

One small point to remember is that if you are using multiple forms from the same data file, you only need to use the actual <catchForms> tag once. To actually put the captured data into your document, you would use multiple instances of the <doForm> tag. Notice how this works in the example below:

```xml
<illustration width="451" height="698">
  <pageGraphics>
    <catchForms storageFile="samples.data"/>
    <doForm name="PF0"/>
  </pageGraphics>
</illustration>

<illustration width="451" height="698">
  <pageGraphics>
    <doForm name="PF1"/>
  </pageGraphics>
</illustration>
```

If you do use repeated <catchForms> tags to point at the same data file, you will get an error message similar to the one below.

ValueError: redefining named object: 'FormXob.PF0'

If this is the case, find the places where you are using the second and subsequent <catchForms> tags and delete them, leaving only the <doForm> tags. (Of course, this doesn’t apply to any doForms which are pointing at other data files. They would still need their own initial <catchForms> tags).

[Note: For the <catchForms> tag to work, you must have PageCatcher installed. In addition, your PageCatcher must be the full version with a .py or .pyc file. The *.exe version of PageCatcher will not work with RML2PDF. If you get the error message "ImportError: catchForms tag requires the PageCatcher product http://www.reportlab.com", then you either do not have PageCatcher installed, or have the wrong version].

The includePdfPages tag

In some circumstances, you may not know how many pages there will be in the PDF file you need to pageCatch. This is the case which <includePdfPages> tag was designed for.
<includePdfPages> is a generic flowable, which means that it can appear at any point in the story.

In its simplest form, an includePdfPages tag will look like this:

```xml
<includePdfPages filename="mypdffile.pdf"/>
```

This will take the PDF file called "mypdffile.pdf", use pageCatcher behind the scenes and include every page in the PDF file in your output. There is also an optional "pages" attribute. This can have either individual pages or ranges. The following are all valid (providing the PDF file is long enough).

```xml
<includePdfPages filename="mypdffile.pdf"/>
<includePdfPages filename="mypdffile.pdf" pages="1"/>
<includePdfPages filename="mypdffile.pdf" pages="1,2,3"/>
<includePdfPages filename="mypdffile.pdf" pages="2,1,1,2,2"/>
<includePdfPages filename="mypdffile.pdf" pages="1-5"/>
<includePdfPages filename="mypdffile.pdf" pages="1,2,4-5"/>
```

There are a number of differences between this tag and the other PageCatcher related tags. Unlike the others, includePdfPages doesn't require you to pre-pagecatch the file you intend to use (so saving you an additional step). It also differs in that the imported PDF gets drawn "over the top" of your exiting document, rather than being used as a background underneath your existing page. So if you have a header or footer in your page template, the included PDF page will overwrite it.

**How includePdfPages works with templates**

When you have an includePdfPages tag in your RML file, RML outputs a page break before the first new page, leaving you on the same page as the last imported one. This allows you to do template switching:

```xml
<setNextTemplate>
  <setNextTemplate name="myIncludePagesTemplate"/>
  <includePdfPages filename="mypdffile.pdf" pages="1,2,3"/>
  <setNextTemplate name="myNormalTemplate"/>
  <nextFrame/>

  <para>
    This text appears on the next normal (non-included) page of your document.
  </para>
</setNextTemplate>
```

This snippet switches to a new page template for use with your included pages, adds in the first three pages from your PDF file, switches back to what is presumably the template you have been using throughout the rest of the document, and outputs a line of text into the next "normal" page of your document. If you don't want any headers or footers behind your PDF pages, define a page template called something like "blank" (in the template section at the head of your document) with a single frame and no decoration on it and use that. If you are content for your included pages to appear over the template you have been using on the previous pages (if the included pages don't have any headers and footers and have large enough margins not clash with the ones you are using in your document, for example), then you can skip both of the setNextTemplate tags completely.

The nextFrame tag is used because the includePdfPages places you at the top of the last included PDF page. This allows you to flow paragraphs or other flowables down your last page. This may be useful if you want to place text in a form, or use some other pre-prepared background for your text. If all you want to do is just drop in a pre-made page, you need this nextFrame to kick you into the next normal page and continue with your document normally.
Look in section 7.6 ("Using multiple frames") for more info on the nextFrame and setNextTemplate tags. Look at the file test\test_016_pagecatcher.rml for an example of this tag in use.

These attributes control the <includePdfPages> tag:

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>filename to include</td>
</tr>
<tr>
<td>pages</td>
<td>The page list</td>
</tr>
<tr>
<td>template</td>
<td>optional page template name</td>
</tr>
<tr>
<td>outlineText</td>
<td>optional outline text</td>
</tr>
<tr>
<td>outlineLevel</td>
<td>optional outline level</td>
</tr>
<tr>
<td>outlineClosed</td>
<td>true for closed outline</td>
</tr>
<tr>
<td>leadingFrame</td>
<td>(yes</td>
</tr>
<tr>
<td>isdata</td>
<td>boolean true if the file is a pageCatcher .data file</td>
</tr>
<tr>
<td>orientation</td>
<td>(0</td>
</tr>
</tbody>
</table>

8.9. Outlines

It can go in either graphics or in a story. (Assigning outline levels to parts of your document (such as paragraphs) allows you to build up a hierarchical structure for your document).

The level specifies how deep in the outline the entry appears. The default level is 0.

closed, if set, hides any children of this outline entry by default. Closed takes Boolean arguments.

Example:

```
<outlineAdd>First outline entry</outlineAdd>
<outlineAdd level="1">sub entry</outlineAdd>
<outlineAdd closed="true">Second outline entry 2</outlineAdd>
<outlineAdd level="1">sub entry 2</outlineAdd>
```

A note about levels: in order to add a level 3 outline entry, the previous outline entry must be at least level 2 (2,3,4,...). In other words, you can "move back" any number of levels, but you can only "move forward" one level at a time.

8.10. Form field tags

An important class of reports contains lots of fields to be traditionally filled in manually by users, like for application forms and similar cases. Sometimes though, these fields are already filled in by some computational process and the user might only need to sign the entire form before leaving it with a bank clerk or sending it off to some destination. RML supports creating both kind of reports by providing a set of special-purpose tags to create such form elements (or fields, widgets...) quite easily. These tags are named <checkBox> <textBox> and <letterBoxes> and are described in the rest of this section.

All these form elements share a lot of features when it comes to what they look like in the document. They all appear as a rectangular shape with some background and border colour, plus some width for the border itself. They also have some sort of text label attached to this rectangle to describe the field's purpose in the context of the report to the human reader. The text inside the field as well as the one in the attached label also should have the usual properties like fontname and size and colour. All form field elements have a boxStyle attribute that
can be used to group attribute names and values and reuse them in many field elements with much less typing eff-
fort.

But there are also specific features that distinguish these form elements from each other. A checkbox does not
contain text, but only a cross (when checked), and a textbox contains one or more lines of text with different pos-
sible alignments, while letterboxes are used for single line mono-space text with visible subcompartments for
each letter.

**Checkboxes**

By default, checkboxes have a very simple style similar to UK bank application forms - an outer rectangle and a
cross which exactly fills it when checked. The attributes control the appearance.

It is also possible to supply your own pair of bitmap images which will be used instead of the default drawing
mechanism - this could be used to provide 3d effects, tick-and-cross icons or whatever is needed. To make use of
this, set the two attributes graphicOn and graphicOff to point to two bitmap files on the disk; these will be
used in preference to the default appearance. Note that they will be stretched to the boxWidth and boxHeight
stated, so it is important to set the same aspect ratio as the underlying image. Also, remember the printing intent
- a 24 pixel bitmap drawn to occupy a 12 point space on a form will be visibly grainy on a good quality printer,
but may be fine on an inkjet.

Because checkboxes do not contain text it can be argued that when they are to be displayed as checked the cross' 
colour should be the same as the border colour. Equally well it can be argued that it should be the same colour
used for text in textboxes. To provide both options checkboxes have an additional colour attribute named
checkStrokeColor which will be used for the cross instead of the border colour if the former is provided.

Note that the label attached to a checkbox is limited to three lines of text now and always appears at the right
margin of the box, but this might be generalised in future versions. The label is expected to be vertically centered
with the box no matter how many lines it is composed of.

The following code creates a row of sample checkboxes providing different values for the most relevant attrib-
utes:

```xml
<checkBox x="0cm" y="0cm" checked="0"/>
<checkBox x="1.5cm" y="0cm" checked="1"/>
<checkBox x="3cm" y="0cm"
  boxWidth="0.75cm" boxHeight="1cm"
  checked="1"/>
<checkBox x="4.5cm" y="0cm"
  boxWidth="0.75cm" boxHeight="1cm"
  lineWidth="0.1cm"
  checked="1"/>
<checkBox x="6cm" y="0cm"
  lineWidth="0.1cm"
  boxFillColor="yellow" boxStrokeColor="green"
  checked="1"/>
<checkBox x="7.5cm" y="0cm"
  lineWidth="0.1cm"
  boxFillColor="yellow" boxStrokeColor="green"
  checkStrokeColor="red"
  checked="1"/>
<checkBox x="9cm" y="0"/>
```
Textboxes

A textbox contains one, but often more lines of text, like in an address field. (Of course, it can also contain no text at all, like for a signature field.) Sometimes it is not clear in advance exactly how much text will go into one such field. Therefore, textbox fields in RML provide a means for automatically resizing the fontsize to shrink the contained text by exactly what is needed to make it fit into the box. This is a two-step process that first tries to shrink the fontsize to make the text fit horizontally. If that is not enough, it is further shrunk to make it also fit vertically. This process is controlled using the attribute `shrinkToFit`.

Because human readers are very sensitive to reading text and get quickly irritated when it does not feel "right", there is a default amount of space (1 point) left between the text and any of the borders of the box, which will be respected by the resizing mechanism. This is hardcoded now, but might become another attribute in the future.

The following code creates a row of sample textboxes illustrating different values for the most relevant attributes: as well as the auto-resizing text feature:

```xml
<textBox x="0cm" y="0cm"
    boxWidth="3cm" boxHeight="1cm"
    label="labeled textbox">some text</textBox>
<textBox x="3.5cm" y="0cm"
    boxWidth="3cm" boxHeight="1cm"
    boxFillColor="yellow" boxStrokeColor="blue"
    label="colorful textbox">some text</textBox>
<textBox x="7cm" y="0cm"
    lineWidth="0.1cm"
    boxWidth="3cm" boxHeight="1cm"
    boxFillColor="yellow" boxStrokeColor="blue"
    label="bold textbox">some text</textBox>
<textBox x="10.5cm" y="0cm"
    boxWidth="3cm" boxHeight="1cm"
    lineWidth="0.1cm"
    boxFillColor="yellow" boxStrokeColor="blue"
    fontName="Times-Bold"
    fontSize="14"
    label="textfancy textbox">some text</textBox>
```
The following code creates a row of sample textboxes illustrating the auto-resizing text feature:

```xml
<textBox x="0cm" y="0cm"
    boxWidth="3cm" boxHeight="1cm"
    fontSize="14"
    label="no resizing">some text</textBox>

<textBox x="3.5cm" y="0cm"
    boxWidth="3cm" boxHeight="1cm"
    fontSize="14"
    label="horiz. resizing">some more text</textBox>

<textBox x="7cm" y="0cm"
    boxWidth="3cm" boxHeight="1cm"
    shrinkToFit="1"
    fontSize="14"
    label="vert. resizing">some text
    some text</textBox>

<textBox x="10.5cm" y="0cm"
    boxWidth="3cm" boxHeight="1cm"
    shrinkToFit="1"
    fontSize="14"
    label="horiz./vert. resizing">some more text
    some text
    some text
    some text</textBox>
```

**Letterboxes**

Letterboxes are intended for single-line text fields where each letter is contained in a subcell, clearly separated from neighbouring cells. This is often seen on official forms where people are expected to write letters of a word at predefined positions. RML provides such letterboxes, too, and they behave mostly like textboxes, but show some significant differences, too.

Usually, the overall width of a form field element is defined by the mandatory `boxWidth` attribute. For letterboxes, though, this is an optional attribute and specifies the width of a subcell containing one letter. The resulting width of the entire box is defined as a multiple of that `boxWidth` attribute with another one named `count`, which is a mandatory attribute.

The following code creates a row of sample letterboxes showing basic attributes:

```xml
<letterBoxes x="0cm" y="7.5cm"
    count="12">letterboxes</letterBoxes>
```
There may also be instances where you want obvious dividers between each subcell, but you don't want entirely separate boxes. Letterboxes have something that allows for this - the optional `combHeight` attribute.

In a 'standard' letterBoxes element (ie one where the combHeight isn't specified), the divider between each individual subcell is a line which fills the whole height of the letterBoxes box. If you specify the combHeight, you can vary the height of this line. This attribute must be a number between zero and one, where "0" means no di-
vider at all and "1" means one that is the whole height of the letterboxes element (and therefore "0.25" is a quarter of the height and so on).

The following code creates a row of sample letterboxes showing the combHeight attribute in use:

```xml
<letterBoxes x="0cm" y="0cm"
combHeight="0"
count="4">comb</letterBoxes>
<letterBoxes x="3.75cm" y="0cm"
combHeight="0.25"
count="4">comb</letterBoxes>
<letterBoxes x="7.5cm" y="0cm"
combHeight="1"
count="4">comb</letterBoxes>
<letterBoxes x="11.25cm" y="0cm"
lineWidth="0.1cm"
boxWidth="0.75cm" boxHeight="0.75cm"
boxFillColor="yellow" boxStrokeColor="blue"
label="combHeight"
fontName="Times-Bold"
fontSize="14"
combHeight="0.5"
count="4">comb</letterBoxes>
```

Using styles with form field elements

As we've already mentioned, checkBox, textBox and letterBoxes all allow you to re-use styles in a similar way to the way you can re-use styles with paragraphs with the boxStyle tag. Like the other style tags (paraStyle and blockTableStyle), boxStyle lives in the stylesheet section, near the start of your document.

boxStyle style can have the following attributes:

**name:**
This is the required attribute which allows you to refer this style by name.

**alias:**
An optional attribute which allows you to refer to your style by another name.

**parent:**
If this is supplied, it must refer to the name of another style. This style with then inherit from the style named.

**fontName:**
An optional attribute, this refers to the font to be used for the main contents of letterboxes or a textbox - it is ignored for checkBoxes.

**fontSize:**
This optional attribute sets the size for the main contents of letterboxes or a textbox - it is ignored for checkBoxes.
alignment:
For letterboxes or a textbox, this optional attribute sets the alignment of the contents of the box. It may be either LEFT, RIGHT, CENTER or CENTRE. It is ignored for checkBoxes.

textColor:
An optional attribute that sets the colour for the main contents in the letterboxes or textbox.

textColor:
An optional attribute that sets the colour for the main contents in the letterboxes or textbox.

labelFontName:
The (optional) tag specifying the font to be used for the label of the letterboxes, textbox or checkBox.

labelFontSize:
The (optional) tag specifying the size of the font to be used for the label of the letterboxes, textbox or checkBox.

labelAlignment:
The (optional) specifying the alignment of the label - may be LEFT, RIGHT, CENTER or CENTRE

labelTextColor:
An optional attribute specifying the colour to be used for the text of the label of a textBox, letterBox or checkBox.

boxFillColor:
An optional tag specifying the colour to be used for the background for a textBox, letterBox or checkBox.

boxStrokeColor:
An optional tag specifying the colour to be used for the lines making up a textBox, letterBox or checkBox.

cellWidth:
An optional tag, specifying the width of a "cell" in a form element. Must be a measurement, but may 'in', 'cm', 'mm' or 'pt' - see the section on 'Coordinates and measurements' for more details on measurements.

cellHeight:
An optional tag, specifying the width of a "cell" in a form element. Must be a measurement, but may 'in', 'cm', 'mm' or 'pt'

Some Examples

As an example of them in use, let's set up two boxStyles, and see what effect they have on letterBoxes, textBoxes and a checkBox.

Firstly, the boxStyles:

```
<boxStyle name="special1"
    labelFontName="Helvetica"
    fontSize="10"
    alignment="RIGHT"
    textColor="red"
    labelFontSize="10"
    labelAlignment="RIGHT"
    labelTextColor="blue"
    boxStrokeColor="red"
    boxFillColor="pink"/>

<boxStyle name="special2"
    parent="special1"
    fontName="Courier"
```
Barcodes

One other tag that may often find use on forms is the barCode tag. As its name implies, this creates a barcode in one of a number of different symbologies.

The three attributes you need to supply for this tag are x and y to position it on the page and code to inform rml2pdf which form of barcode you require.

This is a brief example of what a barcode tag looks like in use, and what it actually produces:

```xml
<barCode x="1cm" y="0" code="Code11">123456</barCode>
```

![Figure 10: The "Code11" barcode](image)

This table shows you the allowed names for the code attribute, along with an example of the barcode produced.

<table>
<thead>
<tr>
<th>Type</th>
<th>Code attribute to use</th>
<th>Example barcode</th>
</tr>
</thead>
<tbody>
<tr>
<td>Codabar</td>
<td>Codabar</td>
<td><img src="image" alt="Codabar example" /></td>
</tr>
<tr>
<td>Code 11</td>
<td>Code11</td>
<td><img src="image" alt="Code11 example" /></td>
</tr>
<tr>
<td>Code 128</td>
<td>Code128</td>
<td><img src="image" alt="Code128 example" /></td>

<td>Standard93</td>
<td><img src="image" alt="Code93 example" /></td>
</tr>
</tbody>
</table>
8.11. Interactive Form Field tags

PDF allows documents to interact with the user provided the renderer supports this. The most common renderers including Acrobat Reader, evince and the various browsers certainly allow this.

RML supports the following interactive form elements

- **textField**

<table>
<thead>
<tr>
<th>Attribute</th>
<th>Meaning</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>name</td>
<td>the radio’s group (ie parameter) name</td>
<td>None</td>
</tr>
<tr>
<td>value</td>
<td>Value of the text field</td>
<td>‘’</td>
</tr>
<tr>
<td>x</td>
<td>the horizontal position on the page (absolute coordinates)</td>
<td>0</td>
</tr>
<tr>
<td>y</td>
<td>the vertical position on the page (absolute coordinates)</td>
<td>0</td>
</tr>
<tr>
<td>width</td>
<td>The widget width</td>
<td>120</td>
</tr>
<tr>
<td>height</td>
<td>The widget height</td>
<td>36</td>
</tr>
<tr>
<td>fontName</td>
<td>The name of the type 1 font to be used</td>
<td>‘Helvetica’</td>
</tr>
<tr>
<td>fontSize</td>
<td>The size of font to be used</td>
<td>12</td>
</tr>
<tr>
<td>maxlen</td>
<td>None or maximum length of the widget value</td>
<td>100</td>
</tr>
<tr>
<td>fillColor</td>
<td>colour to be used to fill the widget</td>
<td>None</td>
</tr>
<tr>
<td>textColor</td>
<td>the colour of the symbol or text</td>
<td>None</td>
</tr>
<tr>
<td>borderWidth</td>
<td>as it says</td>
<td>1</td>
</tr>
<tr>
<td>borderColor</td>
<td>the widget’s border colour</td>
<td>None</td>
</tr>
<tr>
<td>borderStyle</td>
<td>The border style name</td>
<td>‘solid’</td>
</tr>
<tr>
<td>tooltip</td>
<td>The text to display when hovering over the widget</td>
<td>None</td>
</tr>
<tr>
<td>annotationFlags</td>
<td>blank separated string of annotation flags</td>
<td>print</td>
</tr>
<tr>
<td>fieldFlags</td>
<td>Blank separated field flags (see below)</td>
<td></td>
</tr>
<tr>
<td>forceBorder</td>
<td>when true a border force a border to be drawn</td>
<td>False</td>
</tr>
<tr>
<td>relative</td>
<td>if true obey the current canvas transform</td>
<td>False</td>
</tr>
<tr>
<td>multiline</td>

### Button styles

The button style argument indicates what style of symbol should appear in the button when it is selected. There are several choices:
- check
- cross
- circle
- star
- diamond

note that the document renderer can make some of these symbols wrong for their intended application. Acrobat reader prefers to use its own rendering on top of what the specification says should be shown (especially when the forms highlighting features are used).

### Widget shape

The shape argument describes how the outline of the checkbox or radio widget should appear. You can use:
- circle
- square

The renderer may make its own decisions about how the widget should look; so Acrobat Reader prefers circular outlines for radios.

### Border style

The borderStyle argument changes the 3D appearance of the widget on the page. Alternatives are:
- solid
- dashed
- inset
- bevelled
- underlined

### fieldFlags Argument

The fieldFlags arguments can be an integer or a string containing blank separate tokens. The values are shown in the table below. For more information consult the PDF specification.

<table>
<thead>
<tr>
<th>Token</th>
<th>Meaning</th>
<th>Value</th>
</tr>
</thead>

<td>1&lt;&lt;8</td>
</tr>
<tr>
<td>lockedcontents</td>
<td>The contents of the widget are fixed</td>
<td>1&lt;&lt;9</td>
</tr>
</tbody>
</table>

### 8.12. Colorspace Checking

RML >= v2.5 supports a way to ensure the consistent enforcement of color models within a document. For more information on this topic, and examples of when you might want to use different scenarios, please refer to the 'Printing' chapter later in this document.

RGB, CMYK and the use of 'spot colors' such as Pantone can be allowed or disallowed using the 'colorSpace' parameter to the document tag, which can be set to the following values:

- **MIXED** - The default. As in RML versions before 2.5, rgb, cmyk, spot colors and 'named' colors can all be used.
- **RGB** - Permits only the use of RGB colour values.
- **CMYK** - Permits only the use of CMYK colour values.
- SEP - 'Spot Colors' only - all colour values must define a 'spotName' value.
- SEP_BLACK - spot colors, plus shades of grey only.
- SEP_CMYK - spot colors plus cmyk values only.

The use of any color definitions outside the specified type will result in an exception when you try to compile the document, thereby ensuring that, for instance, a document can be produced for CMYK or spot color printing without containing any RGB color definitions.

Any 'named' colours (see appendix A or 'reportlab/lib/colors.py') for black or shades of grey are automatically converted to cmyk/rgb as required. So you can use lowercase 'black' as a color in all models except 'SEP'. However, any other RML 'named' colors such as 'aqua' or 'hotpink' will not be converted.

8.13. Balanced Column

Use the BalancedColumns tag to make a flowable that splits its content flowables into two or more roughly equal sized columns. Effectively n frames are synthesized to take the content and the flowable tries to balance the content between them. The created frames will be split when the total height is too large and the split will maintain the balance.

Attributes
- ncols - Sets the number of columns content should be split
- needed - Sets the minimum space needed by the flowable (default is 72 points)
- spaceBefore - Sets space before the content
- spaceAfter - Sets space after the content
- showBoundary - Draws a boundary box around each column
- leftPadding - Sets left paddings
- innerPadding - Sets inner padding
- rightPadding - Sets right padding
- topPadding - Sets top padding
- bottomPadding - Sets bottom padding

More examples here test_051_balancedcolumns.rml test_051_balancedcolumns.pdf
9. About Cross References and Page Numbers

Many documents (such as this one) require page cross references. For example, the table of contents of this user guide lists the page numbers of the beginnings of each part, chapter, and section.

RML provides several features that support cross referencing and page number calculations. The name and NamedString tags allow forward referencing and the evalString tag allows computations of page numbers (or other computations) inside an RML text. Furthermore, these techniques may be combined with preprocessing methods, such as XSL, the C preprocessor, or the Preppy preprocessor to allow the convenient construction of structures such as tables of contents, indices, or bibliographies.

9.1. the namedString tag and forward references

The namedString tag is similar to the name tag -- it associates a name to a string of text. The namedString tag is more general than the name tag in the sense that it allows other string constructs such as getName in the named text. For example, the following snippet associates the name Introduction with the current page number at the time of formatting.

```
<namedString id="Introduction">The Introduction starts at <pageNumber/></namedString>
```

The name tag does not permit other tags inside the string it names in this manner.

Elsewhere, the RML text may substitute the page number for the introduction using the construct

```
<name id="Introduction" default="this is a default placeholder, used if Introduction is undefined."/>
```

...and this reference to the Introduction name may occur before the Introduction name is defined. For example, the reference may occur at the beginning of the document in the Table of Contents. Whenever a name is referenced before it has been defined the default attribute must be present. In order to prevent possible formatting anomalies the default value should be approximately the same size as the expected final value.

9.2. Multiple pass pdf formatting

RML2PDF resolves names that are referenced before they have been defined by making (by default) at most two passes through the text. If the first pass does not define all names before they have been referenced then RML2PDF formats the document twice.

On the first pass the default value for any undefined name is used for formatting the document (and it may under some circumstances effect the placement of the page breaks). On the second the program uses the resolved value determined on the first pass where the name is referenced.

It is possible to create a chain of references that cannot be resolved, such as:

```
<namedString id="a"><name id="b" default="XXX"/></namedString>
<namedString id="b"><name id="a" default="XXX"/></namedString>
```

In this case RML2PDF will signal an error and fail.

It is also possible to have a chain of references which requires more than one pass to resolve, such as:

```
<namedString id="a"><pageNumber/> is where A is defined, and <name id="b" default="XXX"/></namedString>
... 
<namedString id="b"><pageNumber/> is where B is defined, and <name id="c" default="XXX"/></namedString>
```
By default RML2PDF will fail in this case also, but it is possible to invoke the main processing function RML2PDF.go to allow additional formatting passes. For example as in:

```
  rml2pdf.go(xmlInputText, passLimit=3)
```
to request that the processor execute a maximum of 3 formatting passes before signalling an error if more unresolved names remain.

**WARNING:** A document that requires two formatting passes will take about twice as long to generate as a document that requires only one. For time critical applications it is best to avoid the need for extra formatting passes if they are not needed.

RML documents that do not have references to names before they are defined will not require more than one formatting pass.

### 9.3. Calculated Page Numbers: `evalString`

Some documents require the ability to give "relative page numbers." To meet this requirement RML2PDF includes the `evalString` tag. For example The following `para`:

```
  <para style="contents2">
    <font color="crimson">
      The last page is <getName id="LASTPAGENO" default="-999"/>
      One less than that is
      <evalString default="XXXX">
        <getName id="LASTPAGENO" default="-999"/> - 1
      </evalString>.<br>
      The current page is <pageNumber/>.
      And there are
      <evalString default="XXXX">
        <getName id="LASTPAGENO" default="-999"/> - <pageNumber/>
      </evalString> pages to go.<br>
    </font></para>
```

Performs arithmetic calculations (subtractions) using the current page number and a forward reference to the `LASTPAGENO`, which is presumably defined on the last page. In the context of this document the paragraph evaluates to the following:

**The last page is 1 One less than that is 0. The current page is 66. And there are -65 pages to go.**

An RML document can make use of arbitrary arithmetic calculations using the `evalString` tag, but in practice addition + and subtraction – over page numbers are the most useful.

### 9.4. Generated RML

Although the `name`, `namedString`, `getName` and `evalString` tags can be used to build tables of contents and indices, it is not easy to directly edit RML documents that includes cross reference structures of this kind.

For example to directly add a new section to the this document in RML text it would be necessary to add a new table of contents entry at the top, something like this:

```
  <para style="contents2">
    <getName id="chapterNumber"/>.<seq id="sectionNumber"/>
    Installation
  </para>
```
As well as the text of the section itself

And unless the creator takes great care it may be necessary to adjust various section or chapter numbers in other entries as well.

To avoid this complexity this document is not directly written in RML per se, but is written using a text preprocessor called preppy which automatically builds the table of contents and inserts the appropriate entries at the top (while keeping track of chapter and section numbers).

For very complex documents using a preprocessor of some sort may be advisable.
10. More graphics

10.1. curves

We have seen how you can use the `<lines>` tag to create a number of straight lines with one command. Not all the lines you want to draw will be straight, which is why we have the `<curves>` tag.

Like `<lines>`, `<curves>` must appear in the `pageGraphics` section of your template. Unlike lines, you need to specify 4 points as X-Y co-ordinate pairs (i.e. you need to feed curves sequences of 8 numbers at a time, rather than the 4 you need for lines).

The curves tag produces a Bezier curve. Bezier curves are named after the French mathematician, Pierre Bézier, and are curves that utilize at least three points to define a curve. RML curves use the two endpoints (or "anchor points") and two "nodes".

![Figure 11: A Bezier Curve](image)

In RML, if you give a curve 4 control points (which we shall call (x1,y1), (x2,y2), (x3,y3), and (x4, y4)), the start point of the curve will be specified by (x1,y1) and the endpoint specified by (x4,y4). The line segment from (x1,y1) to (x2,y2) forms a tangent to the curve. The line segment from (x3,y3) to (x4,y4) also forms a tangent to the curve. If you look at an illustration of a Bezier curve, you will see that the curve is entirely contained within the convex figure with its vertices at the control points.

Example:

```xml
<template>
  <pageTemplate id="main">
    <pageGraphics>
      <curves>
        198 560
        198 280
        396 280
        396 560
      </curves>
    </pageGraphics>
  </pageTemplate>
</template>
```
10.2. paths

To connect lines and curves you need to use the <path> tag. This allows you to make complex figures.

Like the other graphics in RML, <path> lives in the <pageGraphics> section at the start of the document.

Initially, you must give a <path> tag x and y attributes to tell it the co-ordinates for the point where this path is going to start. You may also at the same time give it attributes called stroke and fill (which do the same as their counterparts for the basic shapes such as rect and circle), and an additional one called close. If the close attribute is set to "yes" or "1", then once the path is completed, the stroke is finished off by painting a line from the last point given to the first point, enclosing the figure. You may specify attribute autoclose to be one of the values none, pdf or svg; these values alter how automatic closing of sub-paths is handled. The default none just leaves the renderer to handle filling as does pdf, but in the latter case all-subpaths are forced to be closed if fill is set. The last value svg fills and strokes separately (stroke last).

Finally you can control how filling of complex shapes is handled by specifying attribute fillrule to be one of the values none, even-odd or non-zero. The default none means let the pdf canvas decide, but that is currently equivalent to even-odd. For further information on fill rules consult a graphics primer.

The <path> tag has its paired </path> tag. Between these two tags, you can have a number of things:

- You can have a list of pairs of X-Y co-ordinates. If this is the case, a straight line is drawn to each point in turn.
- You can have a paired <moveto/> tag. If this is the case, you need to give an x-y co-ordinate pair between these two tags. The "pen" or "brush" then moves to this point, and any further points or instructions given after this (while still inside the <path> tag) continue onwards from this new point.
- You can have a paired <curvesto/> tag. This is similar to both the <curves> tag and the <moveto> tag discussed above. Inside the pair of <curvesto> tags, you need to give rml2pdf sets of 3 pairs of X-Y co-ordinates at a time. Like <curves>, <curvesto> creates a Bezier curve. However, since it is inside a path object, it already knows one of the points - the start point is assumed to be the last point in the path before the <curvesto> tag. In other words, the "pen" or "brush" is already in a position, and this is taken as the first point for your Bezier curve.
- You can have a <closePath/> tag. This will close the current sub-path; this tag must be followed by a <moveTo> tag or the end of the <path>.

Here is an example of how a <path> looks in action:

```xml
</curves>
</pageGraphics>
<path id="first" x1="0.5in" y1="0.5in" width="20cm" height="28cm"/>
</pageTemplate>
</template>
```
Figure 12: The output from EXAMPLE 7

EXAMPLE 7a

```xml
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM "rml.dtd">
<document filename="example_7a.pdf">
  <template>
    <pageTemplate id="main">
      <pageGraphics>
        <fill color="red"/>
        <stroke color="black"/>
        <path x="247" y="72" fill="yes" stroke="yes" close="yes">
          247 172
          147 172
          147 272
          247 272
          247 372
          347 372
          347 372
          347 272
          447 272
          447 172
          347 172
          347 72
        </path>
        <!-- This completes the first shape: a red cross.--> 
        <moveto>267 572</moveto>
        <!-- This moves the "pen position" 
        <!-- This completes the first shape: a red cross.--> 
      </pageGraphics>
    </pageTemplate>
  </template>
</document>
```
This example has used the 'template/stylesheet/story' form of document. But the story is empty, and we haven't used the stylesheet at all. The following example shows how we can use the 'pageDrawing' form.

**EXAMPLE 7b**

```xml
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM "rml.dtd">
<document filename="example_7b.pdf">
  <stylesheet>
    <!-- Notice that because we have used a "moveto", the final line at the base of the cross is not completed, even though the "close" attribute of the "path" tag is set to "yes" -->
    277 612
    <!-- this acts as the start point for the Bezier curves below -->
    <curvesto>
      147 585
      147 687
      297 792
      447 687 447 585 317 612
    </curvesto>
    327 572
    <!-- We don't need to give the last point because close is set to "yes" -->
  </path>
</pageGraphics>
</pageTemplate>
</stylesheet>
</story>
</document>
```
10.3. grids

The `<grid>` is a graphics tag, and hence lives in the `PageGraphics` section of your RML document. It produces a grid of lines. It takes two arguments - `xs` which is a list of x co-ordinates (separated by commas), and `ys` which is a comma-separated list of y co-ordinates.

Example:

```xml
<grid xs="1cm,2cm,3cm,4cm,5cm,10cm" ys="1cm,2cm,3cm,4cm,5cm,10cm"/>
```

10.4. Translations

In a graphic operation (i.e. a `pageGraphic` or an `illustration`), `<translate>` moves the origin of the drawing.

`<translate>` takes two optional attributes: `dx` and `dy`. Both can be given in any unit that RML understands. `dx` is the distance that the to be moved in the X axis, and `dy` is the distance it is to be moved in the Y axis. They are optional to allow you to only give one of the pair - so moving the origin in only one direction.

Examples:

```xml
<translate dx="55" dy="91"/>
<translate dx="1in"/>
<translate dy="6.5cm"/>
```

This is what a translation with a `dx` of 50 and a `dy` of 50 looks like:
And this is slightly simplified version of the relevant bit of RML:

```
<illustration>
  <lines>
    16 40 116 40
    16 40 16 140
    156 40 256 40
    156 40 156 140
  </lines>
  <setFont name="Times-Roman" size="12"/>
  <fill color="black"/>
  <drawCentredString x="58" y="12">Original</drawCentredString>
  <setFont name="Helvetica-Bold" size="50"/>
  <fill color="red"/>
  <drawString x="16" y="41">X</drawString>
  <translate dx="142"/>
  <setFont name="Times-Roman" size="8"/>
  <fill color="lightgray"/>
  <drawCentredString x="58" y="18">50 pt</drawCentredString>
  <setFont name="Times-Roman" size="12"/>
  <fill color="black"/>
  <drawCentredString x="58" y="12">dx=50 dy=50</drawCentredString>
  <setFont name="Helvetica-Bold" size="50"/>
  <fill color="red"/>
  <translate dx="55" dy="91"/>
  <drawString x="0" y="0">X</drawString>
</illustration>
```

10.5. **scaling**

`<scale>` as its name suggests, allows you to stretch or shrink a graphic.
The `<scale>` tag takes two optional attributes: `sx` and `sy`. `sx` is how much to scale the X axis, and `sy` is how much to scale the Y axis. The scaling does not have to be proportional - omitting one allows you to change the scaling in one direction only. And you can shrink the shape as well as scale it up - an `sx` or `sy` of "2" doubles the size of it, but an `sx` or `sy` of "0.5" halves it.

Scale factors can also be negative. Using an `sx` of -1 and an `sy` of 1 produces a mirror image.

Examples:

```
<scale sx="2" sy="0.25"/>
<scale sx="2"/>
<scale sy="0.5"/>
```

This is what a scale with an `sx` of 2 and an `sy` of 2 looks like:

```
Original

X

sx=2 sy=2
```

10.6. rotations

The `<rotate>` tag allows allows you to rotate a graphic.

`<rotate>` takes one mandatory attributes called `degrees`, which is the number of degrees to rotate the object. A positive number for degrees rotates it *anti-clockwise*, a negative number rotates it clockwise.

When using `<rotate>`, objects are rotated around the current origin. If you want to rotate a specific element of a pageGraphic or illustration, you will have to use a `translate` to move the origin before you do the `rotate`.

If you `translate` to the middle of the page, rotate by 90 degrees and then draw the string "hello", the "hello" will appear starting in the middle of the page going upwards.

Examples:

```
<rotate degrees="90"/> <!-- ANTI-clockwise -->
<rotate degrees="-90"/> <!-- clockwise -->
```

This is what a `<rotate>` looks like with `degrees` set to 45 and -45:
10.7. Skew

<skew> is a transform which distorts both axes of a graphic. It is non-orthogonal - in other words, it is a transformation that does not preserve right angles.

<skew> has two mandatory attributes: alpha and beta. Both are angles - look at the example below to see how they work.

Example:

```
<skew alpha="10" beta="10"/>
```

This is what a skew with an alpha of 10 and a beta of 30 looks like:
10.8. Generic affine transforms

A transform allows the coordinate space to be filtered through a general two dimensional affine transform. All the other coordinate transformations can be defined in terms of a transform. A transform requires 6 numbers $a$, $b$, $c$, $d$, $e$, and $f$ to define the transformation.

$$x' = ax + cy + e$$

$$y' = bx + dy + f$$

For example to specify $a=1$, $b=1.2$, $c=1.3$, $d=1.4$, $e=1.5$ and $f=1.6$ write

```xml
<transform>1 1.2 1.3 1.4 1.5 1.6</transform>
```

[NOTE: All the examples from this section are gathered together in the file example_8.rml].

10.9. About scale, rotate, and skew

- It is very easy to move objects "off the page". If you are doing a `<translate>` as a `<pageGraphic>`, it is possible to put the origin off the visible area of the page. If you are doing a `<translate>` in an `<illustration>`, no checks are performed about whether an object is inside the limits of the `<illustration>` or not, so it is still possible to put it outside the limits of the page and lose it. If you expect to see a diagram and all you get is a blank page, this is the most common cause.

- Scaling has its own version of the same problem. It is possible to `<scale>` an object so that most or all of it is off the page, but it is also possible to `<scale>` something to such a small size that it "shrinks to nothing". Be especially careful when doing scaling with large factors. Something that may have been a small error without the scaling may put your object off the page entirely once you have performed the `<scale>`.

- The scaling operation scales everything - including line widths. If you are taking a huge diagram and scaling it down, the lines may be scaled out of existence. Conversely, if you take something microscopic and enlarge it, you may end up just getting a blob due to the width of the lines being scaled up as well.

- Another thing to remember is that these transformations are incremental - in a series of transforms, each one will modify the output of the one before it. So the order you carry the operations out in is very important. The result of the sequence "translate, rotate, scale" is very different to that of "scale, rotate, translate".
If performing multiple operations, use the order "translate -> rotate -> scale or skew" whenever possible. Using a different order may result in the axes being distorted or other results that lead to an ugly output that isn’t what you were trying to do.

10.10. Bitmapped images

RML also allows you to insert pre-existing images into your PDF files. If you have a graphic file in either the .gif or .jpg format, you can use the <image> tag to insert it into your document.

The <image> tag goes in the <pageGraphics> section at the head of your RML document. It has 5 attributes, 3 of which are mandatory and two of which are optional. The file attribute tells rml2pdf the name of the input file that you want to incorporate into your document, the x and y attributes give the co-ordinates for the bottom left hand corner of where the image will be placed on the page. The optional width and height attributes allow you to specify how big it should be on the page - this means that you can over-ride the normal size of the file and display it at any size that is appropriate. (The x, y, width and height attributes can all be gives in points, mm, cm or inches).

Be very careful when using the width and height attributes. If misused, these attributes can lead to you having a distorted, ugly and out of proportion picture in your final document. Whenever possible, you should use a paint application (e.g. Paintshop Pro, Photoshop, Graphics Converter, GIMP) to save the file at the correct size, and use the correct height and width attributes to the <image> tag. Using larger files and re-sizing inside RML will also lead to the output PDF file being bloated and larger than it needs to be.

This example shows how these tags look in action:

```xml
<pageGraphics>
  <image file="myFile.gif" x="72" y="72"/>
  <image file="myFile.gif" x="369" y="72" width="80" height="80"/>
  <image file="myFile2.jpg" x="72" y="493"/>
  <image file="myFile2.jpg" x="369" y="493" width="80" height="80"/>
</pageGraphics>
```

10.11. Text Fields

To allow the creation of forms we have a graphics tag that allows us to specify that the page should display an entry box.

The <textField> tag goes in the <pageGraphics> section at the at the start of the RML document. It has the following optional attributes: id (the field name), value (the field initial value), x (the field x coordinate), y (the field y coordinate), width (the field width), height (the field height), maxlen (maximum allowable number of field characters) & multiline (whether the field may contain more than one line).

As a convenience the attributes may instead be specified using <param> tags within the body of the <textField> tag. The name attribute of the <param> tag should be one of the above attribute names. If no value attribute or <param> is seen then the contents of the <textField> becomes the initial value of the field.

It is an error to define an attribute more than once
10.12. place, illustration & graphicsMode

place

We have seen how graphics and flowables do not mix in RML. The only exceptions to this are the `<place>` tag and the `<illustration>` tag. `<place>` allows you to put a flowable inside a `<pageGraphics>` or `<illustration>`. You can include a paragraph inside a grid, or a table inside a path.

`<place>` takes 4 attributes, all of which are required. x, and y are the x and y co-ordinates for where you want the flowable placed. width and height are the width and height of the flowable.

Example:

```
<pageGraphics>
  <place x="10.5cm" y="10.5cm" width="9cm" height="9cm">
    <para>Your flowables would go here.</para>
  </place>
</pageGraphics>
```

illustration

You can think of an `<illustration>` as like one of the illustrations in a book. It is a "box" of space on the page which can contain any of the graphics that you would normally expect to find in a `<pageGraphics>` tag. The position of this box depends purely on its place in the story, which means that it can appear anywhere on the page depending on the paragraphs and other flowables around it. This is in contrast to the `<pageGraphics>` which are always placed in a specific place (measured from the origin).

graphicsMode

You can think of a `<graphicsMode>` tag as an `<illustration>` without a size. It allows you to insert arbitrary graphics operations into a story without using up any space. The `<graphicsMode>` tag takes an `origin` attribute which can take the values `local`, `frame` or `page` to specify the coordinate origin to be used. Value `local` means relative to the position where the `<graphicsMode>` tag is in the current frame, `frame` means relative to the frame it is in and `page` means relative to the page (ie absolute).

Example:

```
<illustration width="90" height="90">
  <fill color="red"/>
  <circle x="45" y="45" radius="30" fill="yes"/>
  <setFont name="Times-Roman" size="8"/>
  <drawString x="0" y="0">
    Any graphics could go here.
  </drawString>
</illustration>
```
Notice the symmetry: the `<place>` tag lets you use flowables within a `<pageGraphic>`; the `<illustration>` tag lets you do graphics operations in a box within the flow of the `<story>` (or any story-like context such as a table cell).

The following example shows the use of both `place` and `illustration`:

**EXAMPLE 9**

```xml
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM "rml.dtd">
<document filename="example_9.pdf">
  <template>
    <pageTemplate id="main">
      <pageGraphics>
        <grid xs="1cm,2cm,3cm,4cm,5cm,10cm,20cm" ys="1cm,2cm,3cm,4cm,5cm,10cm,20cm"/>
        <place x="10.5cm" y="10.5cm" width="9cm" height="9cm">
          <title>This is a use of `<i>place</i>`</title>
          <spacer length="15"/>
          <para>
            This is a flowable. In this case, it is in a `<para>` tag, but it could be any flowable. It has been placed inside a grid, but you could put it inside any graphic or `pageGraphics`. Using the `place` tag, you can have complete control over where you want your flowables to appear.
          </para>
          <spacer length="12"/>
        </place>
      </pageGraphics>
    </pageTemplate>
  </template>
</document>
```
You can include Greek: <greek>αβγδ</greek>.

Or even

The red circle you can see is an <i>illustration</i>, not a <i>pageGraphic</i>.

So is the teal colored one.

These are all flowables in the story.
10.13. **spacer**

<spacer> is another tag which does just what the name suggests. A <spacer> inserts an empty element into the page to force other elements downwards or sideways. The spacer tag has two attributes - length is mandatory and refers to the length down the page, and width is optional.

Example:

To produce a spacer 15 points in height and one inch wide, you could do the following:

```xml
<spacer length="15" width="72"/>
```

10.14. **Form and doForm**

A <form> is a group of graphical operations, stored together and given a name. This allows you to group complex graphics together and to re-use them in more than one place with ease. To do this, you would use the doForm tag.

Your form would appear in the pageGraphics section of your RML document (inside the pageTemplate). <doForm> also appears in the pageGraphics section.

The <form> tag has one attribute - a mandatory one called name which identifies the form.

The <doForm> tag executes the sequence of graphical operations defined with a <form> tag. It also has only one mandatory attribute called name.

Example:

```xml
<pageGraphics>
  <form name="myForm">
    <drawString x="0" y="24">
      Your graphic operations would go here.
    </drawString>
    <drawString x="0" y="12">
      There would probably be a lot of them to make up something useful.
    </drawString>
  </form>
  <doForm name="myForm"/>
</pageGraphics>
```

10.15. **Why use forms?**

Why use forms when you can just cut and paste big chunks of text inside your RML document with your favorite text editor or word processor?

The benefits are dramatically cut file sizes, reduced production time and apparently even speeding things up on the printer. If you are going to be using PDF files in any situation where people will be downloading them, massively reduced file sizes will be appreciated by your users. These advantages become even more obvious with multiple similar documents. If you are dealing with a run of 5000 repetitive forms - perhaps payslips or single-page invoices - you only need to store the backdrop once and simply draw the changing text on each page.

Forms should be used whenever you have a graphic that is used repeatedly. It may be something as small as your company logo or some sort of symbol you want to flag interesting bits of text with, or something as large as
a whole page backdrop. As long as you use it repeatedly, it's worth using a form to do it.

Forms don't even have to be created in RML. You can use another application (such as Adobe Illustrator or Word) and distil the output to PDF. You can then use our PageCatcher product to generate the forms, which can then be used from RML.

Look on our web site for more information on PageCatcher: http://www.reportlab.com/pageCatcher/index.html
11. Conditional Formatting

11.1. Introduction

WARNING - this is an advanced topic, intended for programmers trying to deal with difficult layout cases. The tags documented here have the potential to cause hard-to-understand exceptions if not used correctly!

Conditional formatting allows you to include expressions in your RML text which are evaluated or executed when the pdf is actually being built. This means that you can vary the content of your document depending on conditions (such as where you are on the page) which you do not know in advance.

For instance, you may be including dynamic content in your document which is likely to be of variable length. You could use the value of one of the document's internal formatting variables to include or exclude certain content, based on the remaining height of a page or the current page number. One common use is in the case of creating documents for printing: these could be 'padded out' with optional content, to make sure that they are always a 4-page spread. Another useful application would be deciding whether there is space to include a large image or diagram in the present location.

A working example using all of these tags can be found in rlextra/rml2pdf/test/test_039_doc_programming.rml.

Basic programming primitives (assignment, loop, if, while etc.) have been made available as tags. These can be given expressions which can use your own variables, as well as built-in ones available during rendering. All expressions must be valid python literal expressions.

The following internal variables are available to use as conditions:

availableWidth and availableHeight give you the remaining height and width of the current frame.

doc.frame.id returns the id of the current frame

doc.pageTemplate.id returns the id of the current page template

doc.page returns the current page number.

11.2. Tags

The <docIf>, <docElse> and <docWhile> tags allow you to control which content is included and excluded - while, or if, a condition is true or false.

The <docPara> tag allows you to include the value of an expression in the output text. This is useful for debugging document layouts (e.g. temporarily inserting paragraphs like "you are [3] inches down the [left] frame of the [chapter_first_page] template on page [19]"), but you can also use it to display facts you stored earlier.

The value can be formatted using Python format strings - see the test case above for details.

<docAssign> assigns a value to a variable, and <docExec> executes a statement or expression.

The <docAssert> tag allows you to test an expression and raise an exception if it is not true. This can be a useful quality assurance technique. As with the docPara example for debugging, you can include assertions like "I should now be at the top of page 3" or "I should now be in the footer frame".

11.3. Operators

When using docIf or docWhile tags, you can use the following operators to evaluate your conditions:

= < <= > => %
However, bear in mind that the 'greater than' and 'less than' operators must be written in RML as &gt; and &lt;.

11.4. Examples

Some sample code demonstrating several of the conditional formatting tags:

```
<docAssign var='i' expr="3"/>
<docIf cond='i&gt;2'>
  <para style="normal">The value of i is greater than 2</para>
  <docElse/>
  <para style="normal">The value of i is less than or equal to 2</para>
</docIf>
<docWhile cond='i'>
  <docPara expr='i' format='The value of i is %(__expr__)d'/>  
  <docExec stmt='i-=1'/>
</docWhile>
```

results in the output:

```
The value of i is greater than 2
The value of i is 3
The value of i is 2
The value of i is 1
```

As an example of a practical use of conditional formatting, supposing you wanted all your documents to be a certain number of pages. You could use the value of doc.page to decide whether to include or exclude an external 'filler' pdf in your output, and so pad the size of your document:

```
<docIf cond="doc.page == 3">
  <includePdfPages filename="fillerpage.pdf" pages="1" leadingFrame="yes"/>
</docIf>
```

11.5. Reference

Conditional formatting is implemented with the following tags:

```
<docAssign var='' expr=''>
  assigns the value of `expr' to `var', eg to make i=3:<docAssign var='i' expr='3'/>
</docAssign>

<docExec stmt=''>
  executes the statement `stmt', eg to subtract 1 from the value of i:<docExec stmt='i-=1'/>
</docExec>

<docPara expr='' format='' style=''>
  creates a paragraph containing the value of `expr'.
  `format' is an optional attribute which can contain the value of `expr' using the Python string formatting conventions, eg "%(__expr__)s".
  The `style' attribute is optional.
  eg: <docPara expr='i' format='The value of i is %(__expr__)d' style="style.txt"/>

  So if i=2, this results in the text "The value of i is 2"
</docPara>

<docAssert cond='' format=''>
  raises an error containing the value of `format' if `cond' is false, eg:
  eg: <docAssert cond='val', format="val is false"/>
</docAssert>
```

<docIf cond=''/>
<docElse>
    these tags allow flow control while or if the 'cond' attribute evaluates to true. See the example above.
12. Printing

This chapter covers things you will need to know when creating documents for professional printing. Many development projects start off targeting an electronic document, which users will either keep on disk, or print out on an office or home printer. Once you start targeting professional printing presses, things get more complicated. We have tried to write this in a manner accessible to developers with little prior knowledge of print; apologies to professional printers for anything we have 'glossed over' too lightly! The topics covered in this chapter are...

Crop Marks
Bleed
CMYK colours
Overprint/knockout control
Colour separations
Pagination

12.1. Crop Marks

The first difference is the size of the page. Let's say you are in Europe or Asia and have been creating A4 electronic documents from a web site using ReportLab. You then need to produce a different version of the same document for professional printing. The printer wants to be given a slightly larger document, with lines pointing at the corners of the A4 area. They will often be printing on a much larger sheet or roll of paper, and cutting it afterwards.

To automatically create crop marks, use the 'useCropMarks' attribute of the <docinit> tag. This will enlarge the underlying page and draw the needed marks.

```
<docinit useCropMarks="1"/>
```

The intent is that it's reasonable easy now to have a single template which generates print and web versions of the same document, wrapping an <if> statement around the extra attribute in your favourite templating system, without needing to recalculate all the frame and graphics positions for every element on the page.

There is also a separate <cropMarks> tag which you can use within the <docinit> tag, if you wish to modify the page size increase, colour, length, dash pattern and so on for the crop marks; however, we've found the defaults to work fine.
12.2. Bleed

Following on from the above, remember that printers often cut the paper to size. In addition, if they are creating a booklet, they sometimes have to allow for the thickness of inner pages, so they need a little flexibility in where to make the cut. If you have a design with solid colour 'straight to the edge' of the page, cutting can sometimes leave a very fine white line where the colour runs out. Therefore, when a designer wants an area of colour to go 'straight to the edge', they work on a slightly larger page size, and allow the colour to overflow or 'bleed out'. In general printers often ask for at least 3mm of bleed, or about 8 points. So, if you needed to draw a blue background on an A4 sized page (595x842 points), you would be well advised to draw the rectangle from x=-10 to x=+605 - ten points bigger than needed. This will be completely invisible to an end user in a document created for the web; but when you turn on crop marks and the page is enlarged, it will be visible.

There are no features in RML to automatically detect areas of colour near the edge of the page and 'add bleed'; it's your job to do it.

This also applies to bitmap images. If an image runs to the edge of the page, it needs to be sized to very slightly overflow so that it can be cut without risking a white edge.

12.3. CMYK Colours

For professional presses, colours need to be specified either as CMYK, or as 'spot colours' such as those in the Pantone Color Matching System. The CMYK process is a method of printing colour by using four inks - cyan, magenta, yellow, and black. White is the absence of any colour. The Pantone system is a popular 'spot colour' system which describes a set of completely standardized colours, allowing different manufacturers in different locations to ensure that their colours match.

The majority of printed material is produced using the CMYK process. Many Pantone colours have good, well-known CMYK equivalents.

RML allows you to specify colours as CMYK or by spot name, and also provides a mechanism for ensuring that your document sticks to a particular set of colour definition types.

Starting in ReportLab 2.5, a colorSpace attribute can be defined in the <document> tag. This is a declaration of your intent, and it lets us carry out some useful checks on your behalf. It will raise an error if you accidentally use a colour that is not allowed in your colorSpace. Then, to declare a CMYK colour, use the <color> tag, within the <docinit> section at the top:

```
<document filename="test_045_separations.pdf" invariant="1" colorSpace="CMYK">
<docinit>
  <color id="BLUE" CMYK="[1,0.67,0,0.23]"/>
  <color id="CYAN" CMYK="[1,0,0,0]"/>
</docinit>
```
Note that each colour component ranges from 0 to 1, not 0 to 100; you can use any floating point number in between. Designers tend to think in terms of 0-100, but we have chosen to follow the PDF specification.

The ‘id’ is a string you specify. You will then be able to refer to these colours by name elsewhere in a document - for example, you can then set a table cell background or paragraph style to be "BLUE".

The colorSpace attribute is particularly important when dealing with blacks. Many objects in our framework have a default colour of black, and this is an RGB black 'under the hood'. If you set the colorSpace, our framework will 'auto-convert' blacks for you; thus if a table's gridlines or a chart axis is normally drawn in black or a shade of grey (implemented originally as RGB), it will be autoconverted to CMYK black or grey. Many printing presses are able to handle RGB and autoconvert blacks these days, but printers will appreciate it if the PDFs are pure CMYK as it won't raise alarms in their proofing tools.

### 12.4. Images in CMYK documents

Most bitmap images use an RGB colour model. We do NOT yet have safeguards to check images that you include in a CMYK document - the colorSpace checks won't warn you. We might add this checking in a future version. If you are working with a limited number of images, the best approach is to use a professional tool like Photoshop to create CMYK versions of those images, and check you are happy with the colours when printed.

Printers can often handle RGB images in a print job, but it's best to check with them first

### 12.5. Overprint and knockout control

When you create a document with two colours layered on top of one another, there are different ways to combine them. The two alternatives are known as "overprint" and "knockout". Non-primary CMYK colours are, of course, already implemented with a mix of up to four inks. A problem arises when you decide to stack two colours on top of each other. Imagine you have a red and a blue CMYK colour which are each made up of, say, 60% black (the K in CMYK), and you want to draw one on top of the other. Should the software 'merge the colours'? It can't achieve 120% coverage with the black. So, a decision is needed. Either the topmost colour 'knocks out' and replaces anything drawn underneath it, or it 'overprints', allowing the colours to mix, in a manner similar to transparency.

When working with separated colours (see below), the printing mechanics are a little different as each colour is really a bottle of ink; but again, a statement of intent is needed when they overlap - does the top colour replace what's underneath, or allow both to be laid down on the page?

The overprint-versus-knockout choice is rarely used, and works in slightly different ways for CMYK and for separated colours - see the section below. Designers will know when they need it, and the developer merely needs to set a flag.

Some PDF viewing software can simulate this effect on screen (Adobe Reader is one of them); it's necessary to go into the preferences and check a box to see how the document would appear when printed. The default for is usually to for the topmost colour to knock out the colour underneath.

<overprint mode="overprint"> turns on overprint for the drawing operations that follow. You can then set this property to its original value with <overprint mode="knockout"> when you want to go back into the default knock-out mode.
The sample first example above shows cyan, magenta and yellow circles overlapping one another, set to overprint and rendered in Acrobat Professional. Without overprint set in the second example, the inks do not mix on top of each other. Instead, the circles on top knock-out the areas that they cover underneath.

### 12.6. Colour separations

When a PDF document is printed professionally, layers of coloured ink (plates) will be printed one at a time on top of each other, laying down microscopic dots on different angled paths so that more than one colour can be visible. The process colours (CMYK) will normally have a plate each for full-colour printing, but you can define your own spot colour plates to be printed with a specialist "bucket of ink". One common use is for companies to have completely standardised colours in their corporate literature, and to be able to print with just 3 plates instead of the usual 4, which saves money and increases consistency. Another case is using metallic foils or fluorescent paints to enhance areas of your publication, so you might use extra spot colours as well as the CMYK ones. Bear in mind that spot colour inks are usually opaque.

We mentioned above that a colorSpace attribute can be defined in the `<document>` tag. There are two more of these "color spaces" which will be useful for those who are going to use spot colours: 'SEP' will only let you use spot colours you define, and 'SEP_CMYK' will let you define spot colours to use along with the normal CMYK process colours.

```xml
<document filename="test_045_separations.pdf" invariant="1" colorSpace="SEP"/>
```

If using SEP_CMYK, our framework will again 'auto-convert' blacks for you; thus if a table's gridlines or a chart axis is normally drawn in black or a shade of grey (implemented originally as RGB), it will be autoconverted to CMYK black or grey.

An equivalent CMYK colour value needs to be supplied along with a spot name for each printing plate. The CMYK values are usually just to provide an on screen representation and do not need to be accurate, more important is the spot name which is a string that printers can identify the ink such as 'PANTONE 288 CV' or 'PMS_288'. Your printer may advise you on what spot names to use.

You will need to define your spot colours in the `<docinit>` section of your document. The 'id' is what you will use later in the document to refer to that colour, 'CMYK' allows you to see an approximation of your colour in a PDF reader, 'spotName' is how the printer will identify which ink to use for the plate. There is also an optional 'density' attribute which allows you to print with a thinner (or half-tone) layer of ink. If you set a density lower than 1.0, you don't need to fiddle with the CMYK values for on-screen preview; we do that for you.

```xml
<document filename="test_045_separations.pdf" invariant="1" colorSpace="SEP">
<docinit>
    <color id="BLACK" CMYK="[0,0,0,1]"/>
</docinit>
</document>
```
If you have access to Adobe Acrobat Professional or other print pre-flight tool you will be able to preview each of the plates separately and the inks that are used.

The overprint tag is perhaps even more useful when working with spot colours; for example, we have worked with pie charts where the overall document was limited to black and a specific Pantone blue, and the designer was able to create some new tints by stacking the blue and black on top of each other.

12.7. Pagination

A document that is intended to be printed as a bound booklet on a press must always have a page count that is a multiple of four. Even with a different binding technique, documents laid out for print may make use of left and right facing pages which “go together”. RML documents with dynamic content will in many cases be of highly variable length, and not guided by the designer’s "common sense".

It is possible to use the conditional formatting tags in RML to add extra pages and pad out your document to the required length as necessary. For example, we maintain one solution which has a number of optional half-page and full-page advertisements which can be used to ensure the right pagination occurs. See the 'Conditional Formatting' chapter of this guide for more information on this technique.

12.8. More information

We manage a number of solutions which generate documents for professional printing, and have helped clients achieve some interesting effects, but we have limited space here to discuss all of the techniques used. If you are a commercial customer and are seeking to achieve something not documented here, please contact us and we will be happy to assist further.
Part III - Tables

13. Using tables

13.1. Block tables

If you are familiar with HTML, you will understand the basic tags for use with tables in RML. Just as in HTML, you use a tag to tell rml2pdf that a table is on the way (in this case `<blockTable>`); rather than `<table>`), and another one to end it. Within the `<blockTable>` and `</blockTable>` tags, `<tr>` and `</tr>` enclose the rows (from Table Row); and within each table row, `<td>` and `</td>` enclose each individual cell (from Table Data).

So, the simplest `blockTable` in RML will look something like this:

```
<blockTable>
  <tr>
    <td>This</td><td>This</td>
  </tr>
  <tr>
    <td>a</td><td>blockTable.</td>
  </tr>
</blockTable>
```

This produces a table that looks like this:

```
This
is
a
blockTable.
```

Figure 19: A very simple blockTable

In this short example, we are just using plain old vanilla text in the table cells. But we can do more. `<blocktable>` allows you to use paragraphs and the `<para>` tag. This means that you can use bold, italics, colors, fonts, greek... anything you can use in a paragraph. And you can use multiple paragraphs inside a table cell.

```
This is a more complex blockTable.
This is a more complex blockTable.
This is a more complex blockTable.
This is a more complex blockTable.
```

Figure 20: A slightly more complex blockTable

The main thing that makes this slightly more complex than a very simple table is the fact that you must give `rowHeights` and `colWidths` to the `<blockTable>` to use paras. This makes sense - paragraphs fit into the available space on a page. In a table, they must fit into the available space in that cell. If you haven't defined how high and wide that cell will be, then there is no way for rml2pdf to know how to make it flow in that cell. (If you get an error message saying "Flowables cell can't have auto width", then this is the thing to check - you have probably omitted the `rowHeights` or `colWidths`).

When you are using paragraphs inside a table, you must not put any text outside the `<para>`...`</para>` tags. The only exception to this rule is whitespace - you can put spaces and tabs outside the `<para>` tag, but
nothing else.

One other thing to be aware of is that if you use a *para* inside a table, it will ignore the text attributes you have used for that table and instead use the attributes for paragraphs. This can be a plus, (since it allows you to use already defined paragraph styles) but can take you by surprise if weren’t expecting it.

As an example, here is the RML that generated the above table:

```rml
<blockTable
  rowHeights="1.25cm,1.25cm"
  colWidths="4cm,4cm"
>
  <tr>
    <td>
      <para>
        This is a <b>more</b> complex <font color="red">blocktable</font>.
      </para>
    </td>
    <td>
      <para>
        This is a more <i>complex</i> blocktable.
      </para>
    </td>
  </tr>
  <tr>
    <td>
      <para>
        <font face="Helvetica">This is a more complex blockTable.</font>
      </para>
    </td>
    <td>
      <para>
        This is <greek>a</greek> more <font color="blue"><i>complex</i></font> blockta<greek>b</greek>le.
      </para>
    </td>
  </tr>
</blockTable>
```

### 13.2. Block table attributes

This is useful, but there’s a lot more to blockTables than that! The actual `<blockTable>` tag can have a number of optional attributes:

- **style**
  - blockTables can have a style set in the stylesheet in the same way as paragraphs can. If you have set a style for your blockTable, you can refer to it by name with this attribute and apply it to your table. (More details on how to do it appear in the section on the `<blockTableStyle>` tag below).

- **colWidths**
  - If you use this attribute, it takes a comma-separated list of the width of each column in your blockTable. This allows you to vary the widths to match the width of the content of each column. If you do use it, you should be careful to make sure that there is one width given for every column in your table.

- **rowHeights**
  - As colWidths is to columns, rowHeights is to rows. It also takes a comma-separated list, in this case for the heights of the rows in your table.
■ repeatRows
If you have a large table that splits over multiple pages, you may well want certain information appearing on all of them. Column headers are one example of this sort of information. The repeatRows attribute allows you to do this.

repeatRows takes a single number as an argument or a ',' separated list of numbers. In the case of a single number the rows up to and including this row are repeated as "headers" on each section of the table that appears on a new page. If a list of rows is given then this is a zero based list of rows to repeat. So if the list (1,) is given then the first table header will have rows 0 & 1 and any succeeding split table will have the original second row as header. This allows for the first appearance of a table to have additional rows which may be unwanted later.

13.3. Block table styles

blockTables are a flowable, so the actual <blockTable> tag will appear in the story section of your RML document. You can use the <blockTableStyle> tag to set the appearance of your blockTable. This appears in the stylesheet section of your document, and can be used for more than one table. You can set up how all the blockTables in your document will look in one blockTableStyle tag if you want.

The <blockTableStyle> tag is a container for a number of other tags, and needs to be paired with a terminal </blockTableStyle> tag. This works in the same way as <styleSheet></styleSheet>, <pageGraphics></pageGraphics>, and other tags of that sort.

For all of the attributes in blockTableStyle, they refer to a square or rectangular "block" inside the table. This can be as many or as few cells as you want - not necessarily a single cell. This "block" aspect to the attributes is reflected in their names, and gave the table style its name for consistency. (It was felt that since most of these attributes started with "block...", the table tag should itself be called blockTable to keep things simple).

The way the block is described may seem unusual to you if you are not used to programming. The x and y co-ordinates are still given as X,Y (or if you like "Row,Column", rather than the spreadsheet "A1" model), but the numbering starts from 0 rather than 1. This makes the top left-hand cell (0,0). As well as this, the numbers may also be negative. If this is the case, then rml2pdf will count backwards from the end of the last cell. So (-1,-1) is the bottom right hand cell in a table, (-2,-2) is the one up and to the left of that, and so on.

The tags that blockTableStyle can contain are:

■ blockFont
 blockfont sets the font to be used in a block of your table.
 It has one mandatory attribute: name.
 It has four optional attributes: size, leading, start and stop.

■ blockTextColor
 This sets the color that will be used for the text in a block of your table.
 It has one required attribute: colorName.
 It has two optional attributes: start and stop.

■ blockLeading
 This sets the leading that will be used for the text in a block of your table.
 It has one required attribute: length.
 It has two optional attributes: start and stop.

■ blockAlignment
 This sets the alignment of the text in a block of your table.
 It has one required attribute: value. (This can be LEFT, RIGHT, CENTER, or CENTRE).
 It has two optional attributes: start and stop.

■ blockValign
 This sets how the contents of a block of cells in your table are aligned in the vertical direction.
 It has one required attribute: value. (This can be TOP, MIDDLE, or BOTTOM, and defaults to BOT-

Page 93
It has two optional attributes: start and stop.

- **blockLeftPadding**
  This sets the padding (i.e. blank space) between the contents of a cell and left-hand edge of the cell (for a block of cells in your table).
  It has one required attribute: length.
  It has two optional attributes: start and stop.

- **blockRightPadding**
  This sets the padding between the contents of a cell and right-hand edge of the cell (for a block of cells in your table).
  It has one required attribute: length.
  It has two optional attributes: start and stop.

- **blockBottomPadding**
  This sets the padding between the contents of a cell and bottom edge of the cell (for a block of cells).
  It has one required attribute: length.
  It has two optional attributes: start and stop.

- **blockTopPadding**
  This sets the padding between the contents of a cell and top edge of the cell (for a block of cells).
  It has one required attribute: length.
  It has two optional attributes: start and stop.

- **blockBackground**
  This sets the color to be used for the background for a block of cells in your table.
  It has one required attribute: colorName.
  It has two optional attributes: start and stop.

- **lineStyle**
  This allows you to use lines to border your table.
  It has two required attributes: kind (with the options of GRID, BOX, OUTLINE, INNERGRID, LINE-BELOW, LINEABOVE, LINEBEFORE and LINEAFTER), and colorName (which must be the name of a color).
  It has three optional attributes: thickness, start and stop.

### 13.4. More about block tables

A few final things to be aware about when using tables: in RML, table cells (as contained by the `<td>` and `</td>` tags) can only contain one of two different sets of data. Either a table cell can contain string forms (text and the `<getName>` and `<pageNumber>` tags) or it can contain a sequence of flowables (tags such as `<pre>`, `<para>` and the various heading tags). It is **not** possible to mix both of these forms in the same cell (though you can mix them in the same table).

Putting strings into table cells is quicker than using paragraphs. Paragraphs need to work out when to 'wrap' text, strings don't. So you should avoid using paragraphs inside tables unless you really need to (or you don't mind things slowing down).

When you are doing a big database report, wherever possible use separate smaller tables to contain parts of your data rather than one huge table. If you don't use many 'mini-tables' to contain small groups of rows but instead decide to do a big 1,000-row table, you will notice a significant loss of speed in the generation of your output PDF.

This also makes it much easier to design complex grouped reports; for each group header, footer or detail block you can design one table style and keep them all independent of each other.

### 13.5. Using block table styles

Now that we have seen what the `blockTable`'s attributes are, and seen a summary of `<blockTableStyle>`, here are some examples that show you how they can be used together.
The following few pages show a number of examples of blockTables. Each one shows a page with the RML listing, followed by a separate page with the result of that table. Each listing contains comments to point out what each tag involved with the blockTable is doing.
1.1 Example 10 - Colors and fonts in tables

This example show various ways of setting the text color (blockTextColor), font (blockFont) and background color (blockBackground) for regions in a blockTable.

Notice the various ways of specifying a region within the table. Also notice the way we have defined heights for the rows and widths for the columns in the blocktable tag.

EXAMPLE 10

```xml
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM "../rml.dtd">
<document filename="example_10.pdf">
<template>
  <pageTemplate id="main">
    <pageGraphics>
    </pageGraphics>
  </pageTemplate>
</template>
<stylesheet>
  <blockTableStyle id="myBlockTableStyle">
    <!-- This sets a font for every cell from the start of the second row down to the bottom right hand corner -->
    <blockFont name="Courier-Bold" start="0,1" stop="-1,-1"/>
    <!-- This sets a font for the first row -->
    <blockFont name="Helvetica-BoldOblique" size="24" start="0,0" stop="3,0"/>
    <!-- This sets a textColor for all the text in the table -->
    <blockTextColor colorName="black"/>
    <!-- This sets a textColor for the first row -->
    <!-- (Since it comes after the above setting, it overrides it for this row) -->
    <blockTextColor colorName="white" start="0,0" stop="3,0"/>
    <!-- This sets a textColor a column - also overriding -->
    <!-- the first textColor setting for this row -->
    <blockTextColor colorName="blue" start="1,1" stop="1,6"/>
    <!-- This sets a background color for the first row -->
    <blockBackground colorName="red" start="0,0" stop="3,0"/>
    <!-- This sets a background color for the rest of the table -->
    <blockBackground colorName="cornsilk" start="0,1" stop="-1,-1"/>
    <!-- This sets a background color for an individual cell -->
    <!-- This has to go AFTER the above blockBackground, otherwise it would be overpainted by the cornsilk color -->
    <blockBackground colorName="lightcoral" start="3,3" stop="3,3"/>
  </blockTableStyle>
</stylesheet>
<story>
  <title>Example 10 - colors and fonts in tables</title>
  <spacer length = "1cm"/>
  <blockTable style="myBlockTableStyle" rowHeights="3.5cm,2cm,2cm,2cm,2cm,2cm,2cm" colWidths="4cm,4cm,4cm,4cm">
    <tr><td>Cell 0,0</td><td>Cell 1,0</td><td>Cell 2,0</td><td>Cell 3,0</td></tr>
    <tr><td>Cell 0,1</td><td>Cell 1,1</td><td>Cell 2,1</td><td>Cell 3,1</td></tr>
    <tr><td>Cell 0,2</td><td>Cell 1,2</td><td>Cell 2,2</td><td>Cell 3,2</td></tr>
    <tr><td>Cell 0,3</td><td>Cell 1,3</td><td>Cell 2,3</td><td>Cell 3,3</td></tr>
    <tr><td>Cell 0,4</td><td>Cell 1,4</td><td>Cell 2,4</td><td>Cell 3,4</td></tr>
    <tr><td>Cell 0,5</td><td>Cell 1,5</td><td>Cell 2,5</td><td>Cell 3,5</td></tr>
    <tr><td>Cell 0,6</td><td>Cell 1,6</td><td>Cell 2,6</td><td>Cell 3,6</td></tr>
  </blockTable>
</story>
</document>
```

<td>Cell 1,6</td>
<td>Cell 2,6</td>
<td>Cell 3,6</td>
</tr>
</tbody>
</table>

Figure 21: Output table from EXAMPLE 10
1.2 Colors and fonts in table cells

As an alternative to specifying cell properties using block table styles, RML also allows some cell styles to be specified as attributes of the <td> tag.

```
<blockTable colWidths="5cm,5cm" style="myBlockTableStyle1">
  <tr><td>fontName</td><td fontName="Courier">Courier</td></tr>
  <tr><td>fontName</td><td fontName="Helvetica">Helvetica</td></tr>
  <tr><td>fontSize</td><td fontSize="8">8</td></tr>
  <tr><td>fontSize</td><td fontSize="14">14</td></tr>
  <tr><td>fontColor</td><td fontColor="red">red</td></tr>
  <tr><td>fontColor</td><td fontColor="blue">blue</td></tr>
  <tr><td>leading</td><td leading="16">leading is 16</td></tr>
  <tr><td>leading</td><td leading="12">leading is 12</td></tr>
  <tr><td>leftPadding</td><td leftPadding="10">10</td></tr>
  <tr><td>leftPadding</td><td leftPadding="16">16</td></tr>
  <tr><td>rightPadding</td><td rightPadding="10" align="right">10</td></tr>
  <tr><td>rightPadding</td><td rightPadding="24" align="right">24</td></tr>
  <tr><td>topPadding</td><td topPadding="10">10</td></tr>
  <tr><td>topPadding</td><td topPadding="24">24</td></tr>
  <tr><td>bottomPadding</td><td bottomPadding="10">10</td></tr>
  <tr><td>bottomPadding</td><td bottomPadding="24">24</td></tr>
  <tr><td>background</td><td background="pink">pink</td></tr>
  <tr><td>background</td><td background="lightblue">lightblue</td></tr>
  <tr><td>align</td><td align="left">left</td></tr>
  <tr><td>align</td><td align="center">center</td></tr>
  <tr><td>align</td><td align="right">right</td></tr>
  <tr><td>vAlign</td><td vAlign="top">top</td></tr>
  <tr><td>vAlign</td><td vAlign="middle">middle</td></tr>
  <tr><td>vAlign</td><td vAlign="bottom">bottom</td></tr>
</blockTable>
```

*Figure 22: Output table from EXAMPLE 10*
1.3 Example 11 - lines and alignment in tables

This example shows the various vertical and horizontal alignments you can give text in a table, as well as a few ways to use lines.

EXAMPLE 11

```xml
<?xml version="1.0" encoding="iso-8859-1" standalone="no" ?>
<!DOCTYPE document SYSTEM ".../rml.dtd">
<document filename="example_11.pdf">

<template>
  <pageTemplate id="main">
    <pageGraphics/>
    <frame id="first" x1="72" y1="72" width="451" height="698"/>
  </pageTemplate>
</template>

<stylesheet>
  <blockTableStyle id="myBlockTableStyle">
    <!-- Set fonts -->
    <blockFont name="Courier-Bold" size="10" start="0,1" stop="-1,-1"/>
    <blockFont name="Helvetica-BoldOblique" size="10" start="0,0" stop="3,0"/>

    <!-- This sets a textColor for all the text in the table -->
    <blockTextColor colorName="black"/>

    <!-- Another example of blockTextColor -->
    <blockTextColor colorName="green" start="2,2" stop="3,3"/>

    <!-- This sets a blockAlignment for the whole table -->
    <blockAlignment value="CENTER"/>

    <!-- These overrides the above -->
    <blockAlignment value="RIGHT" start="3,0" stop="3,-1"/>
    <blockAlignment value="LEFT" start="0,1" stop="0,-1"/>

    <!-- This sets the vertical alignment for one row -->
    <blockValign value="TOP" start="0,0" stop="-1,0"/>

    <!-- This sets the vertical alignment for one cell -->
    <blockValign value="MIDDLE" start="2,2" stop="2,2"/>

    <!-- Use of linestyles -->
    <lineStyle kind="GRID" colorName="silver"/>
    <lineStyle kind="LINEBELOW" colorName="orangered" start="0,0" stop="-1,0" thickness="5"/>
    <lineStyle kind="LINEAFTER" colorName="maroon" start="1,1" stop="1,6" thickness="1"/>
  </blockTableStyle>
</stylesheet>

VA=value for blockValign
MDLE=MIDDLE for VA in cells 3,2 and 3,3
1.4 Example 12 - images and padding in tables

This example shows images in a table and the way to use the various padding attributes.

For comparison purposes:
The cells that contain pictures in this table are all 166 pixels in height and 161 pixels in width.
Where padding is used, it has a value of 20 pixels horizontally or 40 pixels vertically.

```

### Appendix A - Colors recognized by RML

In this table, the "Color" column gives the name of the color, as recognised in the HTML standard and RML. The hexadecimal number in the "Hex Value" column corresponds to the red, green and blue (RGB) components in the color - the first two digits represent red, the next two green and the last two the blue. (The "0x" just shows it's a hexadecimal number).

</table>
Appendix B - Glossary of terms and abbreviations

baseline
In typography, the imaginary line on which characters sit. The x-height of a font is measured from the baseline to the top of a lowercase x. The descender, for those characters that have one, is defined as the portion of the character that falls below the baseline.

Bezier curves
Named after the French mathematician Pierre Bézier, Bezier curves utilize at least three points to define a curve. The endpoints are called the anchor points, while any other point is known as a node. The curves produced by RML's `<curves>` tag are Bezier curves.

bitmap
A bitmap is a way of storing an image. In bitmaps, each pixel ("picture-cell") is stored as one or more bits of data in a "map" consisting of rows and columns. This means that when you print them out at the size they were created at they look fine, but shrinking or enlarging them leads to them looking blocky and ragged.

JPEG and GIF are both bitmapped graphics formats (as are BMP, PICT and PNG). You can use gifs and jpegs in your RML document with the `<image>` tag.

see also "gif", "JPEG", "image"

Boolean
Named after the nineteenth-century mathematician George Boole, Boolean logic is a form of algebra in which all values are reduced to either TRUE or FALSE (or 0 and 1).

CMYK
A way of specifying a color by its Cyan, Magenta, Yellow and Black ('Key') components. Usually used when referring to pigments - such as in printing.

DTD
Document Type Definition. A term from XML that refers to the file that defines the legal building blocks of an XML document, and the permissible ways to structure it.

empty elements
"Empty" elements are those tags that don't have any content, and are closed with a "/>" at the end of the same tag rather than having a separate closing tag. (e.g. `<getName id="Header.Title"/>` doesn't have a separate `</getName>` tag - the "/>" serves to close it so it doesn't need one). Empty elements are also sometimes known as "singletons".

fill
In RML, the color that a graphic or text item is filled with (as opposed to that of its outline or stroke).

flowables
In RML, "flowables" are items which appear in a story (such as paragraph, spacer, and tables). Flowables are positioned in sequence running down a frame until there is no more room left in that frame, when they are placed in the next frame (or on the next page if necessary). They can not be mixed with graphics.

Flowables include the following tags: `para`, `blockTable`, `title`, `h1`, `h2`, `h3`, `spacer`, `illustration`, `pre` and `plugInFlowable`.

see also "graphics"

GIF
GIF (Graphics Interchange Format) is a bit-mapped graphics file format created by CompuServe in 1987. It is still in common use on the World Wide Web and many other places today.

You can use gifs in your RML document with the `<image>` tag.

see also "bitmap", "JPEG", "image"

graphics
In RML, "graphics" are items which can appear inside the `pageGraphics` and `illustration` tags. Unlike flowables, graphics are explicitly positioned on the page by co-ordinates. They can not be mixed with flowables.
see also "flowables"

**HTML**

**image**
In RML, the "image" tag allows you to use existing graphics files in your document. Currently image supports the GIF and JPEG formats - the two most common formats on the World Wide Web. Most paint applications support both the GIF and JPEG standards.

see also "bitmap", "GIF", "JPEG"

**JPEG**
A lossy compression technique for color images created by the Joint Photographic Experts Group (JPEG). Better for photos than the GIF format, it can use up to 24-bit color and reduce file sizes to about 5% of their normal size. JPEG files are widely used on the World Wide Web and many other places.

(The JPEG format is sometimes known as JFIF, JFI, and JPG as well as JPEG).

You can use JPEG files in your RML document with the `image` tag.

see also "bitmap", "gif", "image"

**jpg**
See JPEG.

**leading**
Leading (pronounced "ledding") is the amount of vertical space allotted for a line of type - the distance between the baseline of one line to the baseline of the next. The name comes from the way that printers used to use thin strips of lead or brass to separate the lines of metal type.

In RML, leading can be supplied as an attribute for the `para` and `paraStyle` tags. It is expressed as the height of the line plus the space between lines. So, for example, using a 12 point font with a leading of 18 gives you a space between lines of 6 points.

You can also have negative leading. By giving a number smaller than the size of font you are using, you can arrange it so that the lines overlap each other.

**orthogonal**
An adjective from mathematics meaning "relating to or composed of right angles".

A non-orthogonal transformation is one which does not preserve right angles. skew is a non-orthogonal transformation.

**PDF**
The Portable Document Format. A format created by Adobe, this is a standard for electronic documents which is platform-independent due to the freely available Acrobat reader. The PDF file format is a complex indexed binary format, with a specification 600 pages long. (RML is much easier!)

**RGB**
A way of specifying a color by its Red, Green and Blue components. Usually used when referring to lights - such as on a computer screen.

**RML**
Report Markup Language. An XML dialect, created by ReportLab, Inc, and and used by their software rml2pdf to produce documents in PDF.

**singleton**
See "empty elements".

**story**
The part of an RML document where the main content of a document goes (if it uses the "template/stylesheet/story" form). This is where text - split into paragraphs by `<para>` tags - is put.
stroke
In RML, the color of the outline of a graphic or text item (as opposed to that of its inside or **fill**.)

stylesheet
This is an obligatory part of an RML document. It is where the styles for paragraphs and **blockTables** are defined (though it can be empty).

**template**
In those RML documents that use the "template/stylesheet/story" form, this is the part of the document where any headers, footers, or background graphic elements are defined.

**vanilla**
Plain, ordinary, or standard [from the default flavor of ice cream in the U.S.]
In RML, you can put in letters, numbers, and punctuation in places which allow you to use "vanilla text", but tags such as `<para>` or `<b>` are not allowed.

**whitespace**
For programmers, whitespace refers to all the characters that appear as blanks on your screen. This includes the space and tab characters, linefeeds, carriage returns, and other more specialised characters.
For designers, whitespace is any areas on a page that aren't the content - the bits that are free of text or artwork.

**XML**
The Extensible Markup Language - a document processing standard set by the World Wide Web Consortium (W3C) - the people who defined the standard for HTML.

Appendix D - Command reference

All attributes are optional unless otherwise specified.

document

<document

    filename="myfile.pdf"  string            required
    compression="0|1|default" PDF compression (default)
    invariant="0|1|default" PDF invariance (default)
    debug="0|1"            Debug document production (0)
    userPass="uuserpw"     Encryption user password
    ownerPass="ownerpw"    Encryption owner password
    encryptionStrength="128|40" Encryption strength    optional
defaults to 128
    permissions="print annotate..." Encryption permissions   optional
allowed are print copy modify annotate
default is print

>

</document>

Above is the story based form for the document tag.
Encryption will only take place if a userPass is specified.

document

<document

    filename="myfile.pdf"  string            required
>

<pageInfo>...</pageInfo> optional
<pageDrawing>...</pageDrawing> one or more
</document>

Above is the PageDrawing based form for the document tag.

The document tag is the root tag for RML documents. Every RML document must contain on and only one document tag. There are two forms for a document: the story form and the pageDrawing form.
**docinit**

```xml
<docinit

blockTableStyle
Table Style Block Descriptors

**blockFont**

```xml
<blockFont
    name="TimesRoman" string required
    size="8" measurement
    leading="10" measurement
    start="4" integer
    stop="11" integer
/>
```

**blockLeading**

```xml
<blockLeading
    length="10" measurement required
    start="4" integer
    stop="11" integer
/>
```

**blockTextColor**

```xml
<blockTextColor
    colorName="pink" string required
    start="4" integer
    stop="11" integer
/>
```

**blockAlignment**

```xml
<blockAlignment
    value="left" "left", "right", or "center"
    start="4" integer
    stop="11" integer
/>
```
**blockLeftPadding**

```xml
<blockLeftPadding
    length="0.2in" measurement required
    start="4" integer
    stop="11" integer
/>
```

**blockRightPadding**

```xml
<blockRightPadding
    length="0.2in" measurement required
    start="4" integer
    stop="11" integer
/>
```

**blockBottomPadding**

```xml
<blockBottomPadding
    length="0.2in" measurement required
    start="4" integer
    stop="11" integer
/>
```

**blockTopPadding**

```xml
<blockTopPadding
    length="0.2in" measurement required
    start="4" integer
    stop="11" integer
/>
```

**blockBackground**

```xml
<blockBackground
    colorName="indigo" string required
    start="4" integer
    stop="11" integer
/>
```
**blockValign**

```xml
<blockValign
  value="left"
  start="4"
  stop="11"
/>
```

**blockSpan**

```xml
<blockSpan
  start="4"
  stop="4"
/>
```

**lineStyle**

```xml
<lineStyle
  kind="BOX"
  thickness="4"
  colorName="magenta"
  start="4"
  stop="11"
  count="2"
  space="2"
  dash="2,2"
/>
```

The line command names are: GRID, BOX, OUTLINE, INNERGRID, LINEBELOW, LINEABOVE, LINEBEFORE and LINEAFTER. BOX and OUTLINE are equivalent, and GRID is the equivalent of applying both BOX and INNERGRID.

**bulkData**

```xml
<bulkData
  stripBlock="yes"
  stripLines="yes"
  stripFields="yes"
  fieldDelim="",""
  recordDelim="",""
/>
```
<excelData
    fileName="somefileName"
    sheetName="somesheetName"
    range="A1:B7"
    rangeName="somerangeName"
/>
